The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390

- **Fax** your question to the NASA Access Help Desk at (301) 621-0134

- **E-mail** your question via the **Internet** to help@sti.nasa.gov

- **Write** to:

Scientific and Technical Aerospace Reports

STAR

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the International Aerospace Database, managed by the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

Front Matter
A typical citation and abstract sample explaining the standard format, which includes codes for ordering reports.

An Abstract Section
Citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.

An Index Section
- Subject
- Personal author
- Corporate source
- Contract number
- Report number.

Appendix
A guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors companion journals, *International Aerospace Abstracts (IAA),* and *NASA Open Volumes on Aerospace (NOVA).* They list abstracts of the open literature on aerospace subjects available worldwide. IAA is available from the American Institute of Aeronautics and Astronautics (AIAA), and *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Reports found in *STAR* are also available through the NASA online retrieval service, RECON, and the Aerospace Database through DIALOG.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) 1

02 AERODYNAMICS 2
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY 17
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION 23
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE 25
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION 27
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER 27
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL 30
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) 33
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) 35
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS 38
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) 39
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES 40
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION 40
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING....41
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE 42
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics*, and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION .... N.A.
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER 45
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion*, and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) 55

24 COMPOSITE MATERIALS 56
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY 75
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS 81
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS 87
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS 97
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power*, and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING 99
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) 126
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR 131
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety*, and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING 140
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER 147
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY 169
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS 172
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING 177
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY 183
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS 184
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) 190

43 EARTH RESOURCES AND REMOTE SENSING 229
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION 262
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION 264
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS 273
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY 283
Includes weather forecasting and modification.

48 OCEANOGRAPHY 287
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) 299

52 AEROSPACE MEDICINE 303
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES 313
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT 315
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY 318
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) 318

60 COMPUTER OPERATIONS AND HARDWARE 319
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE 320
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS 335
Includes computer networks and special application computer systems.

63 CYBERNETICS 338
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS 341
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY 347
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS 348
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS 348
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) 350
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS 357
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS 358
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS 370
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS 374
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS 384
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS 394
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS 408
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) 415
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT 416
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE 418
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS 422
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY 422
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION 422
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) 423

89 ASTRONOMY 423
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS 425
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION 433
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS 482
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION 484
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

PERFORMANCE AND ROTOR LOADS MEASUREMENTS OF THE LYNX XZ170 HELICOPTER WITH RECTANGULAR BLADES
Benton H. Lau, Alexander W. Louie (Sterling Software, Inc., Palo Alto, CA.), Nicholas Griffiths (Westland Helicopters Ltd., Yeovil, England.), and Costantinos P. Sotiriou (Westland Helicopters Ltd., Yeovil, England.) May 1993 362 p
(RTOP 505-59-36)
(NASA-TM-104000; A-93039; NAS 1.15:104000) Avail: CASI HC A16/MF A03

This report presents the results of a series of flight tests on the Lynx XZ170 helicopter with rectangular blades. The test objectives were to explore the flight envelope and to measure the performance and structural loads of the Lynx main-rotor system. The tests were conducted as part of the British Experimental Rotor Program (BERP) under a contract with the Ministry of Defense in England. Data were acquired for steady-level flights at five weight coefficients. Some flight conditions were tested at beyond the retreating-blade stall boundary, which was defined by a predetermined limit on the pitchlink vibratory load. In addition to documenting the flight conditions and data, this report describes the aircraft, particularly the rotor system, in detail. Author

MICROGRAVITY VIBRATION ISOLATION TECHNOLOGY: DEVELOPMENT TO DEMONSTRATION Ph.D. Thesis - Case Western Reserve Univ.
Carlos M. Grodsinsky Sep. 1993 273 p
(RTOP 694-03-03)
(NASA-TM-106320; E-8067; NAS 1.15:106320) Avail: CASI HC A12/MF A03

The low gravity environment provided by space flight has afforded the science community a unique area for the study of fundamental and technological sciences. However, the dynamic environment observed on space shuttle flights and predicted for Space Station Freedom has complicated the analysis of prior 'microgravity' experiments and prompted concern for the viability of proposed space experiments requiring long term, low gravity environments. Thus, isolation systems capable of providing significant improvements to this random environment have been developed. This dissertation deals with the design constraints imposed by acceleration sensitive, microgravity experiment payloads in the unique environment of space. A theoretical background for the inertial feedback and feedforward isolation of a payload was developed giving the basis for two experimental active inertial isolation systems developed for the demonstration of these advanced active isolation techniques. A prototype six degree of freedom digital active isolation system was designed and developed for the ground based testing of an actively isolated payload in three horizontal degrees of freedom. A second functionally equivalent system was built for the multi-dimensional testing of an active inertial isolation system in a reduced gravity environment during low gravity aircraft trajectories. These multi-input multi-output control systems are discussed in detail with estimates on acceleration noise floor performance as well as the actual performance acceleration data. The attenuation performance is also given for both systems demonstrating the advantages between inertial and non-inertial control of a payload for both the ground base environment and the low gravity aircraft acceleration environment. A future goal for this area of research is to validate the technical approaches developed to the 0.01 Hz regime by demonstrating a functional active inertial feedforward/feedback isolation system during orbital flight. A NASA IN-STEP flight experiment has been proposed to accomplish this goal, and the expected selection for the IN-STEP program has been set for Jul. of 1993. Author (revised)

FEDERAL AVIATION ADMINISTRATION AVIATION FORECASTS FY 1993-2004
Feb. 1993 229 p
(AD-A265611; FAA-APO-93-1) Avail: CASI HC A11/MF A03

This report contains the Fiscal Years 1993-2004 Federal Aviation Administration (FAA) forecasts of aviation activity at FAA facilities. These include airports with FAA control towers, air route traffic control centers, and flight service stations. Detailed forecasts were made for the major users of the National Aviation System: air carriers, air taxi/commuters, military, and general aviation. The forecasts have been prepared to meet the budget and planning needs of the constituent units of the FAA and to provide information that can be used by state and local authorities, the aviation industry, and the general public. The lethargy of both the U.S. and world economies during the past several years has caused the aviation industry to experience continuing financial losses. However, the outlook for the 12-year forecast period is for moderate economic growth, stable real fuel prices, and modest inflation. Based on these assumptions, aviation activity for fiscal year 2004 is forecast to increase by 24.6 percent at towered airports and 27.0 percent at air route traffic control centers. The general aviation active fleet and hours flown are forecast to increase by 7.0 and 18.1 percent, respectively, during the same time period. Scheduled domestic revenue passenger miles (RPM's)are forecast to increase 58.3 percent, scheduled international RPM's are forecast to increase by 115.3 percent, and regional/commuter RPM's are forecast to increase by 145.1 percent. DTIC

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

AN INVESTIGATION ON THE EFFECTIVENESS OF THE PIPING INTERFERENCE REMOVAL SYSTEM FOR STOL AIRCRAFT WIND TUNNEL TESTS [STOL ZENKI MOKEI HAIKAN KANSHOU JOKYU SOUCHI KOUKA SHIKEN]
Hitoshi Takahashi, Teruomi Nakaya, Masayoshi Noguti, Osamu Nonaka, Hideo Hoshino, and Takashi Inoue Apr. 1992 28 p In JAPANESE
(NAL-TM-647; JTN-93-80448) Avail: CASI HC A03/MF A01

The piping interference removal system, developed at the National Aerospace Laboratory (NAL) to reduce the interference on the balance caused by the high-pressure piping, was studied using force measurements from wind tunnel tests. A model was employed which utilized a simulated engine powered by high pressure air through the high pressure air hoses. It was founded that the interference effects on the measured forces were negligible; thus, no piping interference corrections were necessary for STOL aircraft wind tunnel tests used with the simulated engine. System usefulness was also confirmed since little difference occurred between the resultant aerodynamic coefficients and those obtained in tests using the previous high-pressure air hose system. NONLINEAR ASPECTS OF TRANSONIC AEROELASTICITY Ph.D. Thesis
Hema Sandhyarani Murty 1992 213 p
Avail: Univ. Microfilms Order No. DANN73808

Flutter analysis of airfoils in transonic flow has traditionally assumed linearity of the aerodynamic loads and moment with motion amplitude. However, the nonlinear nature of the mixed flow, incorporating large amplitude shock wave motion, may significantly invalidate the linearity assumption. The effect of nonlinear transonic aerodynamics on the flutter analysis is analyzed utilizing a simplified linear structural model. The aerodynamic conditions under which these effects are significant are determined for specific cases using the NACA 64A010 airfoil. In order to accurately determine the aerodynamic loads and moment, an unsteady full potential code was developed. This code was joined to an algorithm which integrates the structural equations of motion in time. A flutter analysis based on the assumption of linear aerodynamics was carried out to determine the neutral stability conditions defined by a set of structural and aerodynamic parameters. These neutral stability conditions were then used in the structural equations of motion with nonlinear aerodynamic loads and moment. These equations were then integrated in time to determine the response of the system. If the time response was not neutrally stable, then the structural parameter, Mu, the airfoil-to-air mass ratio was varied until the time response was neutrally stable. If the difference in the value of the 'nonlinear' Mu to 'linear' Mu was greater than 10 percent, then that case was considered to exhibit significant nonlinearities. Dissert. Abstr.

ESTIMATION OF CRITICAL VALUES AND VIBRATION CHARACTERISTICS ON SUPERSONIC DELTA WINGS. PART 1: ON-LINE TIME SERIES ANALYSIS OF STATIONARY RANDOM RESPONSE [CHOUONSOKU DERUTAYOKU NO SHINDOU TOKUSEI TO ANTEI GENKAI NO SUITEI. DAI 1 POU: TEIJOUNA FUKISOKU OUTOU NO ONRAIN JIKEIRETSU KAISEKI]
Yasukatsu Andou, Yuuji Matsuzaki, Masakatsu Minegishi, Hiroshi Ejiri, Seizou Sakakibara, Junichi Noda, and Kiyomichi Ishida Apr. 1992 20 p In JAPANESE
(NAL-TR-1153; JTN-93-80434; DE93-767977) Avail: CASI HC A03/MF A01

A personal computer based, on-line time series analysis system is described which estimates the flutter boundary and vibration-mode parameter of a flutter model. The system software is written in BASIC (Beginner's All-purpose Symbolic Instruction Code) and uses an autoregressive process. Ground vibration and wind tunnel flutter tests were conducted on supersonic delta wing models to enable system evaluation. Stationary random response of the wings was subsequently applied into the system and its practical use was confirmed using the estimated results. Author (NASDA)

THEORETICAL AND EXPERIMENTAL METHODS IN HYPERSONIC FLOWS [LES METHODES THEORIQUES ET EXPERIMENTALES POUR L'ETUDE DES ECOULEMENTS HYPERSONIQUES]
Apr. 1993 575 p Symposium held in Torino, Italy, 4-8 May 1992 Original contains color illustrations
(AGARD-CP-514; ISBN-92-835-0694-4) Copyright Avail: CASI HC A24/MF A04

Papers prepared for the AGARD Fluid Dynamics Panel Symposium on theoretical and experimental methods in hypersonic flows held on 4-8 May 1992 are presented. The objectives of the Symposium were to (1) report and assess the advances being made by the AGARD community on the development and application of theoretical methods and experimental techniques for simulating hypersonic flows over aerospace vehicles; (2) highlight outstanding problem areas; and (3) establish pointers to aid in the planning and implementation of future research programs. Major topics covered by the Symposium were testing techniques and instrumentation, computational methods and physical modeling, and validation and accuracy assessment. For individual titles, see N94-10422 through N94-10465.

Design studies are underway for a variety of hypersonic flight vehicles. The National Aero-Space Plane will provide a reusable, single-stage-to-orbit capability for routine access to low earth orbit. Flight-capable satellites will dip into the atmosphere to maneuver to new orbits, while planetary probes will decelerate at their destination by atmospheric aerobraking. To supplement limited experimental capabilities in the hypersonic regime, computational fluid dynamics (CFD) is being used to analyze the flow about these configurations. The governing equations include fluid dynamic as well as chemical species equations, which are being solved with new, robust numerical algorithms. Examples of CFD applications to hypersonic vehicles suggest an important role this technology will play in the development of future aerospace systems. The computational resources needed to obtain solutions are large, but solution adaptive grids, convergence acceleration, and parallel processing may make run times manageable.

The Hermes spaceplane will represent a major step in the European space activities. It will be placed into orbit by the heavy-lift launcher Ariane 5. After completion of the mission, it will glide back from low earth orbit to its landing site. In order to take the different problems linked to the ascent and the reentry phases, an aerodynamic strategy was set up. A global review of this strategy will be made. It will contain elements on the available and necessary tools (experimental and theoretical) for the Hermes definition and qualification phases. Some aspects such as the design of the Hermes spaceplane will also be highlighted. It will review the different constraints that will be faced during the ascent and reentry phases. Constraints may come from mission requirements such as crossrange capability or from technology limits such as thermal limits on the thermal protection system or from guidance and control requirements. A new methodology was selected in order to take constraints and uncertainties into account in the design oriented towards qualification of the Hermes spaceplane. The main line of this methodology is the projection on a typical reentry trajectory of the uncertainties in the aerodynamic characteristics checked on control points.

EXPERIMENTAL RESULTS IN AERODYNAMIC STABILITY AND CONTROL OF A TSTO CONFIGURATION **c08**
T. Gottmann and G. Cucinelli *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 14 p (For primary document see N94-10421 01-02)
Copyright Avail: CASI HC A03/MF A04

A Winged Launcher Configuration (WLC) in a Two Stage To Orbit (TSTO) version has to fly through a wide range of angles-of-attack and Mach numbers (roughly -3 deg is less than or equal to alpha is less than or equal to 20 deg and 0.2 is less than or equal to Ma is less than or equal to 7.0). This and the requirements for horizontal take-off and landing in Central Europe, and the special separation maneuver at a hypersonic Mach number, causes a wide range of new aerodynamic and aerothermodynamic problems. Especially the problem of stability and control is increased by the wide alpha-Mach range and possibly strong engine effects. The main tasks of the experimental investigations of a TSTO configuration are to establish a data base to support the whole design process of Winged Launcher Configurations, to provide a validation base for CFD codes and to understand the very complicated problems which dominate stability, control, and stage separation aerodynamics. A generic baseline configuration of a TSTO was developed at MBB (lower and upper stage), which satisfies all requirements so far. To be able to test this configuration in all occurring speed regimes, a titanium model (size 1:160) was manufactured with an acceptable size to fit into most wind tunnels for sub-, super-, and hypersonic Mach numbers, especially at DLR in Germany and FFA in Sweden. The main part of the presentation deals with trends of the TSTO configuration in aerodynamic stability and control over the entire Mach regime, showing that some aerodynamic characteristics change significantly with increasing Mach number. Because all aerodynamic forces and moments must be balanced by the engine or aerodynamic controls to obtain reasonable flight conditions, statements regarding absolute stability and control features cannot be set up within this investigation, but tendencies can be given. Major emphasis is placed on the flap efficiency at high Mach numbers which exhibits a strongly nonlinear behavior. The separation of the upper stage was investigated in a special test phase, which shows the enormous changes in longitudinal characteristics caused by interference effects in close proximities between upper and lower stage.

Two models equipped with trailing edge flaps were tested at a Mach number of 8.2. A simple flat plate model was used to understand how control effectiveness is influenced by transition, bluntness, and incidence, while a cropped-delta-wing spaceplane configuration has emphasized the important three-dimensional effects arising from the geometry chosen. Schlieren photographs were used to visualize the flow, and pressure measurements on the windward surface of the spaceplane model showed any regions of separation. Encapsulated liquid crystals were used to obtain an overall picture of the heat transfer distribution and to highlight the three-dimensional structure of the flow.

Several analytical aerodynamic design tools that were applied to the Pegasus air-launched space booster were evaluated using flight measurements. The study was limited to existing codes and was conducted with limited computational resources. The flight instrumentation was constrained to have minimal impact on the primary Pegasus missions. Where appropriate, the flight measurements were compared with computational data. Aerodynamic performance and trim data from the first two flights were correlated with predictions. Local measurements in the wing and wing-body interference region were correlated with analytical data. This complex flow region includes the effect of aerothermal heating magnification caused by the presence of a corner vortex and interaction of the wing leading edge shock and fuselage boundary layer. The operation of the first two missions indicates that the aerodynamic design approach for Pegasus was adequate, and data show that acceptable margins were available. Additionally, the correlations provide insight into the capabilities of these analytical tools for more complex vehicles in which design margins may be more stringent.

Design of ballistic planetary entry probes for planned ESA/NASA Titan, Mars, and Earth-Return missions is discussed with emphasis on the common design constraints. The choice of aeroshell configuration and some of the simple design rules are outlined which are used initially at pre-feasibility stages. These include the influence of body dynamics, conventional aerodynamics, and aerothermodynamics. Prediction of the aerothermodynamic environment and influence of uncertainties in the basic physics and chemistry are seen to dominate. Analysis methodology and some of the ESA sponsored experimental program which was initiated to tackle the lack of basic chemistry data is discussed. Author (revised)

The two high enthalpy shock tunnels in Aachen and Gottingen, Germany are described. Both of these are shock tunnels operating in the reflected mode. The Aachen tunnel has a heated driver and the Gottingen tunnel has a free piston driver. The Aachen tunnel has been in operation for a number of years already and the characteristic operating conditions of this tunnel are described. The tunnel in Gottingen (HEG) is currently being established. The first commissioning results of this tunnel are being described. The Aachen tunnel TH2 covers a testing range in air from perfect gas behavior to real gas behavior with significant oxygen dissociation effects. The HEG was designed to operate in the flow regimes where also significant nitrogen dissociation dominates. Author (revised)

DESIGN AND PRODUCTION OF INSULATED WIND TUNNEL MODELS OF THE HERMES SHUTTLE FOR HEAT TRANSFER MEASUREMENTS AT HYPERSONIC SPEEDS **c09**
L. Visintini and C. Couedor (Dassault Aviation, Istres, France.) *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 9 p (For primary document see N94-10421 01-02)
Copyright Avail: CASI HC A02/MF A04

Among all kinds of wind tunnel experiments undertaken up to now by Dassault Aviation to develop the European HERMES shuttle, those relative to heat transfer measurements could be the last to be fully accomplished. To some extent, one could say that difficulties came from sensors themselves, from their integration conditions, and finally from additional similitude parameters not considered before. The paper introduces to Dassault Aviation so-called 'insulated models' and describes the ongoing activity developed with the collaboration of AerMacchi. The models have the purpose of making heat transfer measurements with correct simulation of surface temperatures due to its demonstrated effect on boundary layer transition. A number of pathfinder models were developed for this purpose: after a first attempt made by using a machinable ceramic, the second one was intended for surface temperatures up to 400 C and was made in a temperature resistant composite material, and the third one, able to sustain skin temperatures above 1000 C, is made by an insulating ceramic coating on a steel core. The fluid-dynamic and technological aspects related with the design and manufacture of these models are described.

The arc heated wind tunnel (LBK) of the DLR is a useful device for high enthalpy tests of thermal protection systems of spacecrafts. The facility is described concerning its capability in simulation of the gas-surface interaction phenomena at the stagnation point of space vehicles. The working area of the tunnel resulting from tests on SiC-samples is discussed and compared with other arc heated wind tunnels. To support experimental works on the LBK numerical computations including flow solutions based on chemical equilibrium, frozen chemistry, and chemical nonequilibrium were performed. It is shown that the flow field downstream the nozzle throat is nearly frozen. Finally, the upgrading concept and the proposed performance of the facility are discussed. Author

LOCAL MEASUREMENT OF TEMPERATURES AND CONCENTRATIONS: A REVIEW FOR HYPERSONIC FLOWS
C. Dankert (Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Goettingen, Germany.), R. Cattolica (California Univ., San Diego.), and W. Sellers *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 10 p (For primary document see N94-10421 01-02)
Copyright Avail: CASI HC A02/MF A04

The quality of reentry simulation for Shuttle, HERMES, Sanger, and NASP systematically suffers from the strong non-equilibrium of rotational and vibrational temperature due to the rapid acceleration of the test gas in the nozzle. Therefore the determination of temperatures is necessary and, if possible, preferable by a non-intrusive technique. The specific interests of this review are optical techniques such as electron beam fluorescence, laser-induced fluorescence, and coherent anti-Stokes Raman scattering. The capabilities available for local measurements with temporal resolution and quantitative accuracy are discussed for velocity, temperature, density, species concentrations, and fluctuations due to turbulence. The applicability of these methods of measurement is presented and discussed for the coming topic in aerothermodynamics: experimental techniques of hot gases in high enthalpy flows. Author

PRESSURE AND FORCE MEASUREMENTS ON MODELS SET IN HYPERSONIC FLOWS: A REVIEW

Charles G. Miller *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 11 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

A review of measurement techniques used to obtain aerodynamic forces and moments and surface/flow field pressures for models tested in impulse hypersonic-hypervelocity facilities and in conventional-type hypersonic wind tunnels is presented. Although force and moment measurement techniques presently used in hypersonic wind tunnels are relatively unchanged from the 1960's and 1970's, significant advances have recently been made for impulse facilities. For both hypersonic wind tunnels and impulse facilities, the state-of-the-art has advanced via refinements, improved test techniques, and advances in semiconductor technology, data acquisition systems, and computers. The introduction of electronically scanned pressure systems over a decade ago 'revolutionized' pressure measurements in hypersonic wind tunnels and a second 'revolution' is impending with the development and application of optical, two-dimensional, global pressure measurement techniques. The development and continued refinement of miniature piezoresistive transducers has provided the capability to perform detailed surface pressure measurements on relatively small, complex models in impulse facilities; these transducers also provided the capability for intrusive flow field pressure measurements with miniature survey rakes. This paper is based upon a session of the NATO Advanced Research Workshop, New Trends in Instrumentation for Hypersonic Research held at the ONERA La Fauga Facility in France during the week of 27 Apr. 1992. The discussion includes some of the frontiers of the technology of flow visualization and spectroscopy as well as a discussion of the current development needs and trends. Included in the discussion are optical integrated measurements such as resonance absorption, schlieren, interferometry, and holographic methods. The discussion shows that while the technology is mature in a broad sense, a significant number of new development areas exist such as resonant holography and phase shifting holographic interferometry. The maturity of the technology makes it immediately applicable to many problems and the untapped potential offers considerable room for improvement of existing capability. The methods which are described can be used in harsh environments and have the potential for becoming flight test diagnostics for the measurement of temperature, density, constituency, and velocity. A CFD VALIDATION ROADMAP FOR HYPERSONIC FLOWS c34

Joseph G. Marvin *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 16 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

A roadmap for computational fluid dynamics (CFD) code validation is developed. The elements of the roadmap are consistent with air-breathing vehicle design requirements and related to the important flow path components: forebody, inlet, combustor, and nozzle. Building block and benchmark validation experiments are identified along with their test conditions and measurements. Based on an evaluation criteria, recommendations for an initial CFD validation data base are given and gaps identified where future experiments would provide the needed validation data. SYNTHESIS OF THE WORKSHOP ON HYPERSONIC FLOWS FOR REENTRY PROBLEMS

Remi Abgrall, Jean-Antoine Desideri, Michel Mallet (Avions Marcel Dassault, Saint-Cloud, France.), Jacques Periaux (Avions Marcel Dassault, Saint-Cloud, France.), Pierre Perrier (Avions Marcel Dassault, Saint-Cloud, France.), and Bruno Stoufflet (Avions Marcel Dassault, Saint-Cloud, France.) *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 23 p Workshop held in Antibes, France, Jan. 1990 and Apr. 1991 (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

One of the most challenging problems of modern aerospace engineering is undoubtedly the prediction of hypersonic flows around reentry vehicles. Indeed this challenge has many aspects: defining the appropriate physical model for these flows is the first difficulty since very complex physical and chemical phenomena take place during the reentry phase; moreover, temperature, velocity, and enthalpy are very high, density very low, making the reentry conditions very difficult to reproduce in ground-based experiments. Thus, in the past two decades, important efforts in computational fluid dynamics have been made employing supercomputers to simulate these complex flows. However, most simulation tools were originally designed for transonic or supersonic flow applications and later extended; these usually contain imperfect models, and also still have to be improved to permit the accurate prediction of hypersonic flows. This situation has motivated strong international cooperative efforts including three Europe/US Short Courses on Hypersonics and two sessions (Part 1 and 2) of the scientific workshop organized by INRIA and GAMNI which took place in Antibes, France. Part 1 brought together a group of experts active in hypersonics, and promoted direct comparisons of codes and experiments. The main objective of part 2 was to improve the quality of both experimental and computational results, and evaluate numerical codes by code-to-code or code-to-experiment comparisons, and permit a better confidence in the prediction tools to be used in the design of hypersonic vehicles. The presentation is aimed at reporting the main conclusions as

they were expressed at the meeting by experts, including some of their recommendations regarding the validation of numerical codes.

PROBLEMS IN THE VALIDATION OF CFD CODES THROUGH COMPARISON WITH EXPERIMENT **c34**
David S. Dolling *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 15 p (For primary document see N94-10421 01-02)
Copyright Avail: CASI HC A03/MF A04

Accurate predictions of the effects of shock wave turbulent boundary layer interactions are of particular importance in the design of hypersonic vehicles. Such flows can generate intense heat transfer rates and pressure levels, complex large-scale unsteady separated flows, and large-amplitude fluctuating loads. With increased reliance on computation, it is critical that the predictions are accurate. Thus, it is imperative that such codes be validated and calibrated and deficiencies be identified and rectified. Comparison of the predictions of computational fluid dynamics (CFD) codes with experimental data is the key element of the validation process. However, drawing meaningful conclusions about the strengths and weaknesses of solution methodologies or of turbulence models from these comparisons is not a trivial task. As recently stated by Jameson, 'Simply comparing experimental data with numerical results provides no way to distinguish the source of the discrepancies, whether they are due to faulty numerical approximation or programming, or to deviations between the math model and true physics.' The conclusions drawn may be quite misleading if it is not clearly understood what the computations represent and what the experimental data represent. This paper discusses why it is important to know how experimental mean flowfield and surface data being used for comparison with CFD are generated. If the flowfields exhibit local or global large-scale unsteadiness, then such mean measurements, which form the bulk of the existing data base, may mask the underlying flow physics and be inappropriate for comparison with computation. FLOW DEVELOPMENT IN A CIRCULAR PIPE IN THE UTIAS/RPI M = 8.3 GUN TUNNEL
J. P. Sislian, Z. He, and R. L. Deschambault *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 13 p Sponsored in part by Natural Sciences and Engineering Research Council (For primary document see N94-10421 01-02)
(Contract F33615-87-C-2748)
Copyright Avail: CASI HC A03/MF A04

The investigation is concerned with the understanding of the structure of the hypersonic flow developed in a circular pipe. The experiments were conducted in the University of Toronto Institute for Aerospace Studies (UTIAS)/Ryerson Polytechnical Institute (RPI) gun tunnel at a freejet Mach number of 8.30 and Reynolds number based on the pipe diameter, Re = 2.44 x 10(exp 6). Wall static pressure, as well as in-stream static and pitot pressure measurements at several sections in the pipe, shed some light into the physical nature of the considered flow. The measurements indicate that shocks generated in the pipe flow are primarily oblique. Measurements near the pipe axis and in wave structures presented some difficulties. Further work is needed to clarify certain features of the investigated flow. The presented results may guide the development of computational fluid dynamic codes applicable to hypersonic pipe flows. Copyright Avail: CASI HC A03/MF A04

Wind tunnel measurements on a flat plate, ogive cylinder, and a compression ramp at zero angle-of-attack are compared to computational fluid dynamics (CFD) predictions of the flow parameters. These models provide a zero-pressure gradient, favorable-pressure gradient, and an adverse-pressure gradient flow condition, respectively. Results are presented for surface pressure and temperature distributions, boundary layer surveys, heat transfer rates, and local skin friction coefficients. Test conditions were varied over a free-stream Reynolds number range of 0.45-9.1 (10 exp 7) per meter, at a nominal Mach number of 6. Wind tunnel measurements on the three models were made using static pressure ports, embedded thermocouples, coaxial heat transfer gauges, slug calorimeters, Preston tube skin friction devices, and skin friction force balances. Boundary layer profiles were measured with total temperature and pitot pressure probes and with laser doppler velocimetry. Parabolized Navier-Stokes and full Navier-Stokes code predictions of the measured parameters are compared to experimental measurements. Results indicate surface pressure distributions are easily predicted by the CFD codes used and for the simple geometries modeled. For CFD codes which predict the surface heat transfer rate accurately, the local skin friction coefficient agrees to within 7-10 percent of the measured data for favorable-pressure gradient and zero-pressure gradient configurations. For adverse-pressure gradients, the code used did not predict skin friction values accurately, although heat transfer predictions matched the data. Large gradients in the hypersonic boundary layer require dense grids near the model surface in order for CFD codes to accurately predict the surface heat transfer rate and the local skin friction coefficient. Additionally, dense grids in the streamwise direction are necessary to properly resolve the boundary layer for adverse-pressure gradients. Author (revised)

EXPERIMENTAL, ANALYTICAL, AND COMPUTATIONAL METHODS APPLIED TO HYPERSONIC COMPRESSION RAMP FLOWS
G. Simeonides, W. Haase (Dornier Luftfahrt G.m.b.H., Friedrichshafen, Germany.), and M. Manna *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 12 p (For primary document see N94-10421 01-02)
Copyright Avail: CASI HC A03/MF A04

Experimental data on fully laminar and transitional shock wave boundary layer interactions in two-dimensional compression corners are provided and used for the validation of two full Navier-Stokes solvers, as well as for checking the capabilities and limitations of simple analytical prediction methods. Viscous pressure interaction, free interaction, and inviscid oblique shock theory are found to predict well the pressure levels on the flat plate upstream of the interaction, within the separated region and downstream of the interaction, respectively. The reference temperature theory is found to perform well in attached flow regimes both upstream and downstream of the interaction region, and to provide the basis for a universal peak heating correlation law. Full Navier-Stokes computations are necessary, however, to predict the extent of the interaction region and the associated influence upon the pressure distribution (control effectiveness) as well as the detailed heat transfer distribution. To achieve this, very fine gridding coupled with the use of strict convergence criteria (based on the evolution of the location of the separation point rather than on standard density residuals) is shown to be necessary. It is finally shown that, although sophisticated turbulence models need to be further developed before the detailed characteristics of fully turbulent shock wave boundary layer interactions may be predicted, transitional interactions (where transition typically occurs in the neighborhood of reattachment) may be adequately handled by algebraic turbulence models 'switched on' just downstream of reattachment. A closely coupled computational and experimental aerodynamics research program was conducted on a hypersonic vehicle configuration at Mach 8. Aerodynamic force and moment measurements and flow visualization results were obtained in the Sandia National Laboratories hypersonic wind tunnel for laminar boundary layer conditions. Parabolized and iterative Navier-Stokes simulations were used to predict flow fields and forces and moments on the hypersonic configuration. The basic vehicle configuration is a spherically blunted 10 deg cone with a slice parallel with the axis of the vehicle. On the slice portion of the vehicle, a flap can be attached; flap deflection angles of 10 deg, 20 deg, and 30 deg were used. Comparisons are made between experimental and computational results to evaluate the quality of each and to identify areas where improvements are needed. This extensive set of high-quality experimental force and moment measurements is recommended for use in the calibration and validation of computational aerodynamics codes. Author (revised)

Critical issues concerning the modeling of low density hypervelocity flows where thermochemical nonequilibrium effects are pronounced are discussed. Emphasis is on the development of validated analysis tools, and the activity in the NASA Ames Research Center's Aerothermodynamics Branch is described. Inherent in the process is a strong synergism between ground test and real gas computational fluid dynamics (CFD). Approaches to develop and/or enhance phenomenological models and incorporate them into computational flowfield simulation codes are discussed. These models were partially validated with experimental data for flows where the gas temperature is raised (compressive flows). Expanding flows, where temperatures drop, however, exhibit somewhat different behavior. Experimental data for these expanding flow conditions is sparse and reliance must be made on intuition and guidance from computational chemistry to model transport processes under these conditions. Ground based experimental studies used to provide necessary data for model development and validation are described. Included are the performance characteristics of high enthalpy flow facilities, such as shock tubes and ballistic ranges. Author (revised)

A coordinated computational and experimental study was made of blunt-body flows with nonequilibrium chemistry. The temperature range was such that significant dissociation of oxygen was expected but very little dissociation of nitrogen. Both pure oxygen, O2 and O, and air, treated computationally using a five species (O2, N2, NO, N, and O) model were studied. Results obtained using different published values of the chemical rate coefficients were compared and assessed for a model problem. The effects of size (i.e., Damkohler number) and freestream velocity were also investigated. The flow computations used an explicit timemarching method based on a TVD version of the MacCormack predictor-corrector scheme. A point implicit TVD method was developed to deal with the stiffness problems introduced by the finite rate chemistry. Interferograms of the flow obtained in a shock tunnel are compared with the computational results. The bow shock wave shape and the shock detachment which are dependent on the degree of chemical reaction and thermal excitation of the gas show that the calculation method is promising. THERMODYNAMIC MODEL OF AIR IN CHEMICAL EQUILIBRIUM c77

D. Giordano and L. Marraffa *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 15 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

A thermodynamic model of air in chemical equilibrium is described. The model includes 13 chemical components, namely N, O, Ar, e(-), NO, N2, 02, N(+), 0(+), Ar(+), NO(+), N2(+), O2(+), and is treated as a mixture of perfect gases. The constant pressure specific heats of the components constitute the basic information to be provided and they are assumed to be specified in the form of interpolating polynomials valid in assigned subranges of a given temperature range; the polynomial expressions were structured to preserve generality and flexibility with respect to temperature range subdivisions and polynomial coefficient data published by various sources. The set of the chemical reactions includes 47 reactions, of which only 9 are independent. The equilibrium composition is solved, in terms either of mass fractions or molar fractions, according to the method of the equilibrium constants and numerically computed by an iterative scheme which proves fast and accurate. A FORTRAN program was written to perform the numerical calculations of the thermodynamic properties and of the equilibrium composition. Temperature range subdivisions and polynomial coefficient data can be implemented at will. Presently, the program includes data from 3 US sources and 1 Soviet source. Discrepancies in the constant pressure specific heats of the components deriving from the choice of different data sources are put in evidence. The process to validate the program is described and validation evidence is given in the relevant diagrams. Author (revised)

THREE-DIMENSIONAL HYPERSONIC RAREFIED FLOW CALCULATIONS USING DIRECT SIMULATION MONTE CARLO METHOD

M. Cevdet Celenligil (Middle East Technical Univ., Ankara, Turkey.) and James N. Moss *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 12 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

A summary of three-dimensional simulations on the hypersonic rarefied flows in an effort to understand the highly nonequilibrium flows about space vehicles entering the Earth's atmosphere for a realistic estimation of the aerothermal loads is presented. Calculations are performed using the direct simulation Monte Carlo method with a five-species reacting gas model, which accounts for rotational and vibrational internal energies. Results are obtained for the external flows about various bodies in the transitional flow regime. For the cases considered, convective heating, flowfield structure and overall aerodynamic coefficients are presented and comparisons are made with the available experimental data. The agreement between the calculated and measured results are very good. Author (revised)

A numerical method was developed to compute the axisymmetric flow over blunt slender bodies with high accuracy to enable reliable analysis of the stability properties. The flow field is obtained using the Beam-Warming method to solve the thin-layer Navier-Stokes equations. The code was thoroughly validated and applied to compute the laminar flow over a long blunt cone with 7 deg half-angle at M(sub infinity) = 8. The linear stability of this flow was analyzed with highly accurate finite-difference and spectral methods. The results are compared with previous numerical studies and the experimental data of Stetson et al. Author (revised)

The effects of nonequilibrium chemistry and three dimensionality on

the stability characteristics of hypersonic flows are discussed. In two-dimensional (2-D) and axisymmetric flows, the inclusion of chemistry causes a shift of the second mode of Mack to lower frequencies. This is found to be due to the increase in size of the region of relative supersonic flow because of the lower speeds of sound in the relatively cooler boundary layers. Although this shift in frequency is present in both the equilibrium and nonequilibrium air results, the equilibrium approximation predicts modes which are not observed in the nonequilibrium calculations (for the flight conditions considered). These modes are superpositions of incoming and outgoing unstable disturbances which travel supersonically relative to the boundary-layer edge velocity. Such solutions are possible because of the finite shock stand-off distance. Their corresponding wall-normal profiles exhibit an oscillatory behavior in the inviscid region between the boundary-layer edge and the bow shock. For the examination of three-dimensional (3-D) effects, a rotating cone is used as a model of a swept wing. An increase of stagnation temperature is found to be only slightly stabilizing. The correlation of transition location (N = 9) with parameters describing the crossflow profile is discussed. Transition location does not correlate with the traditional crossflow Reynolds number. A new parameter that appears to correlate for boundary-layer flow was found. A verification with experiments on a yawed cone is provided.

REAL GAS AND SURFACE TRANSPIRATION EFFECTS UPON SWEPT LEADING EDGE HIGH SPEED FLOW INCLUDING TRANSITION
D. I. A. Poll *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 16 p (For primary document see N94-10421 01-02)
Copyright Avail: CASI HC A03/MF A04

The extension of simple methods for the prediction of skin friction and heat transfer at an infinite-swept attachment line to cover the hypervelocity flight regime including the effects of surface transpiration is considered. The analysis is limited to the situation where the flow is in thermochemical equilibrium everywhere. Real gas effects are identified and their influence is quantified. The importance of freestream conditions and attachment-line inclination are assessed. Consideration is also given to the issue of boundary layer transition.

In view of the prevailing discrepancies between experiment and theory with regard to instabilities in hypersonic flow, an extended theoretical approach is studied. For hypersonic flow past a pointed cone Thin Layer Navier Stokes solutions are compared to similarity solutions with different modeling of viscosity-temperature laws. The formulation of the stability equations in curvilinear coordinates allows a discussion of various representations of the local body metric. A systematic sensitivity study of basic state profiles and spatial amplification rates is performed. It is found that the improved agreement with the experiment in the viscous first mode region is equally due to the extended stability analysis, where cone metric is specified, and the extended mean flow solution as well. In the second mode region the major improvement results from the more complete basic state formulation, however, the close agreement with measured growth rates is only achieved when the stability analysis is based on conical metric.

Results from current studies on slender bodies of revolution tested at a nominal Mach number of 9 are presented. It concentrates on the case of a spherically-blunted cone, providing kinetic heating data for laminar, turbulent, and transitional flow regimes. Nose blunting exerts a powerful control on the location of transition, and the quantitative measurements of this location using thin film gauge techniques are supported by flow visualization using liquid crystal thermography. We also discuss work and plans for two other studies which are in their early stages: these are a cavity-induced separation and the development of turbulent boundary layers under controlled pressure gradients. Preliminary computations using a high resolution Navier-Stokes code are also presented.

An implicit finite-volume method for investigating viscous flows in a state of chemical and vibrational nonequilibrium in nozzles is presented. The ideal-fluid flux terms are calculated by a decentered Roe-type scheme that is second order in space, and the viscous fluxes are determined using a centered scheme. The numerical fluxes and the sources terms are coupled completely at the implicit stage. The proposed method is illustrated by application to two flow configurations: (1) a test case from the Antibes Workshop on hypersonic flows, and (2) a nozzle flow in the ONERA F4 wind tunnel.

The interest in hypersonic flow was renewed through the Hermes European program. A better knowledge of chemical and thermodynamical nonequilibrium processes connected with aerodynamic aspects is needed to study the reentry phase of the shuttle Hermes. Around this research area, many numerical approaches, taking into account more or less complicated nonequilibrium models, were developed. In order to validate these computations, different hypersonic facilities were built or are being designed. In these facilities, the hypersonic air flow is obtained at the exit of a convergent-divergent nozzle in which the reservoir enthalpy level is such that dissociation of diatomic molecules occurs. It is of upmost importance to be able to compute the flowfield in these nozzles, in order to ascertain the upstream conditions in front of the model being studied. The aim is a numerical study of hypersonic laminar inviscid/viscous flows, taking into account, on one hand, a complete description of chemical and thermodynamical nonequilibrium processes in an inviscid flow and on the other hand, the viscous effects through solving the Navier-Stokes equations for a real gas mixture with a simplified model for the vibrational nonequilibrium effects of diatomic species.

Some studies made during a collaboration between the Italian Aerospace Research Center (CIRA) and Alenia D.V.D., whose aim is to provide proper validation of CFD codes in hypersonic flow regime, are described. In fact, in our opinion, the combination of numerical and experimental tools should give a better theoretical understanding of such types of flow. Numerical methods able to give accurate prediction of hypersonic flows in hypersonic wind tunnels were developed and the results obtained by calculations are compared with experimental data gathered by CIRA. Alenia equilibrium three-dimensional Euler solver, originally developed to solve transonic flows and now extended to hypersonic ones, and a non-equilibrium two-dimensional Euler solver, developed by CIRA for the Hermes program, were used to get test chamber predictions. A CFD-BASED AERODYNAMIC DESIGN PROCEDURE FOR HYPERSONIC WIND-TUNNEL NOZZLES **c09**

John J. Korte *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 10 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A02/MF A04

A new procedure which unifies the best of current classical design practices, computational fluid dynamics (CFD), and optimization procedures is demonstrated for designing the aerodynamic lines of hypersonic wind-tunnel nozzles. The new procedure can be used to design hypersonic wind tunnel nozzles with thick boundary layers where the classical design procedure has been shown to break down. An efficient CFD code, which solves the parabolized Navier-Stokes (PNS) equations using an explicit upwind algorithm, is coupled to a least-squares (LS) optimization procedure. A LS problem is formulated to minimize the difference between the computed flow field and the objective function, consisting of the centerline Mach number distribution and the exit Mach number and flow angle profiles. The aerodynamic lines of the nozzle are defined using a cubic spline, the slopes of which are optimized with the design procedure. The advantages of the new procedure are that it allows full use of powerful CFD codes in the design process, solves an optimization problem to determine the new contour, can be used to design new nozzles or improve sections of existing nozzles, and automatically compensates the nozzle contour for viscous effects as part of the unified design procedure. The new procedure is demonstrated by designing two Mach 15, a Mach 12, and a Mach 18 helium nozzles. The flexibility of the procedure is demonstrated by designing the two Mach 15 nozzles using different constraints, the first nozzle for a fixed length and exit diameter and the second nozzle for a fixed length and throat diameter. The computed flow field for the Mach 15 least squares parabolized Navier-Stokes (LS/PNS) designed nozzle is compared with the classically designed nozzle and demonstrates a significant improvement in the flow expansion process and uniform core region. The requirement of the design process of hypersonic vehicles to predict flow past entire configurations with wings, fins, flaps, and propulsion system represents one of the major challenges for aerothermodynamics. In this context computational fluid dynamics has come up as a powerful tool to support the experimental work. A couple of numerical methods developed at MBB designed to fulfill the needs of the design process are described. The governing equations and fundamental details of the solution methods are shortly reviewed. Results are given for both geometrically simple test cases and realistic hypersonic configurations. Since there is still a considerable lack of experience for hypersonic flow calculations an extensive testing and verification is essential. This verification is done by comparison of results with experimental data and other numerical methods. The results presented prove that the methods used are robust, flexible, and accurate enough to fulfill the strong needs of the design process. Author (revised)

An international collaboration on the development of multi block flow solvers using structured grids is presented. The flow equations are solved by the finite volume method using a space centered, explicit time marching scheme augmented by artificial dissipation terms. Implicit residual smoothing is used to accelerate convergence to steady state. The multi block flow solvers are written on top of the MEMCOM data base system which provides the data structure, and use a Dynamic Memory Manager to allocate the necessary storage for each block. The Euler solver EULMB can be used to simulate hypersonic flows including equilibrium and nonequilibrium air chemistry. Recently the Euler solver has been extended to solve the Navier Stokes equations for laminar caloric perfect gas flows (NSMB flow solver). Calculated results for the calculation of the flow over a double ellipsoid and over the HERMES space shuttle are presented. The inviscid calculations around HERMES showed that if one is only interested in the aerodynamic coefficients, equilibrium air calculations are sufficient. Parallel computations showed that the communication overhead between blocks is less than 0.5 percent, showing that the multi block concept is very promising for using parallel computers efficiently. The development of an algorithm for the solution of the compressible Euler equations at high Mach numbers on unstructured tetrahedral meshes is described. The basic algorithm is constructed in the form of a central difference scheme plus an explicit added artificial viscosity based upon fourth order differences of the solution. The stability of the solution in the vicinity of strong gradients is preserved by the incorporation of an additional artificial viscosity based upon a second order difference. Higher order accuracy is regained by using the ideas of flux corrected transport to limit the amount of added viscosity. The solution is advanced to steady state by means of an explicit multi-stage time-stepping method. The computational efficiency of the complete process is improved by incorporating an unstructured multigrid acceleration procedure. A number of flows of practical interest are analyzed to demonstrate the numerical performance of the proposed approach. Author

ON THE ACCURACY AND EFFICIENCY OF CFD METHODS IN REAL GAS HYPERSONICS

D. Drikakis and S. Tsangaris (National Technical Univ., Athens, Greece.) *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 15 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

A study of viscous and inviscid hypersonic flows, using generalized upwind methods, is presented. A new family of hybrid flux splitting methods is examined for hypersonic flows. A hybrid method is constructed by the superposition of the Flux Vector Splitting (FVS) method and second order artificial dissipation in the regions of the strong shock waves. The conservative variables on the cell faces are calculated by an upwind extrapolation scheme third order of accuracy. A second order accurate scheme is used for the discretization of the viscous terms. The solution of the system of equations is succeeded by an implicit unfactored method. In order to reduce the computational time a Local Adaptive Mesh Solution (LAMS) method is proposed. LAMS method combines the mesh sequencing technique and the local solution of the equations. Local solution of either Euler or Navier-Stokes equations is applied in the region of the flow field where numerical disturbances are died out slowly. Validation of the Euler and Navier-Stokes codes is obtained for hypersonic flows around blunt bodies. Real gas effects are introduced via a generalized equation of state. Extension of numerical methods in real gas hypersonics is presented for the hybrid FVS method and a Riemann solver. Author

Copyright Avail: CASI HC A03/MF A04

A detailed comparison of numerical results obtained by solving the Euler equations for the inviscid flow over delta wings in reentry configurations is presented. The investigation involves a side-by-side comparison between independently developed upwind Euler solvers at VKI (M3D) and NASA Johnson Space Center (E3D) using identical grids. In both solvers the governing equations are integrated by means of time marching finite volume shock capturing methods, based on a cell centered upwind evaluation of the cell face fluxes and nonlinear limiters. High resolution schemes are obtained via MUSCL characteristic variable extrapolation to ensure total variation diminishing (TVD) properties and therefore monotonic discontinuity capturing. Further comparisons are made with several published results by other authors based on both upwind and central discretizations. The present results contribute in asserting the high resolution upwind TVD schemes as the most reliable numerical technique to handle the strong discontinuities typical of high speed flows. The performances of the two upwind solvers are satisfactory and the numerical results in good agreement. However, the important issue of reaching a grid converged solution for the present complex three-dimensional inviscid flow problems was not achieved. Author (revised)

The objective is to present results obtained with the Navier Stokes code used by Dassault Aviation for aerothermal reentry problems. We will emphasize the strategy employed and only give an outline of the numerical technique developed for each solver involved in the calculation. The method is designed to have a wide range of application. It involved a sequence of calculations using different modules and interfaces. This tool is not only multi-codes but also multi-computers. The preparation of the initial solution sets for computations were performed on our IBM ES 9000/820 with MVS ESA operating system, and most of the computation was done on a NEC SX3 (at NLR in the Nederlands) and on a CRAY YMP (at C.I.R.A. in Italy) with UNIX operating system. We shall present a validation case using the complete sequence, and afterwards a number of critical points of microaerothermodynamics. The validation test case is a Complete Hermes canopy of the 0.0 geometry (shape number 185 in Dassault catalog). A model of this shape was tested in R3CH ONERA wind tunnel yielding experimental results that are used for comparison. For the flight cases we plan to compute: various canopy shapes; a meteorite impact on the Hermes noze cap; and joint between tiles (in first tile position). Author (revised)

THERMAL AND CHEMICAL NON EQUILIBRIUM HYPERSONIC FLOW COMPUTATIONS

F. Grasso and V. Bellucci *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows Apr. 1993 11 p (For primary document see N94-10421 01-02)

Copyright Avail: CASI HC A03/MF A04

A two-temperature model was developed for the description of thermal and chemical nonequilibrium viscous hypersonic flows. The model employs a vibrational coupling factor as proposed by Treanor and Marrone, and it uses a model based on a non-preferential removal of vibrational energy. The technique relies on a finite volume approach based on a second order accurate Total Variation Diminishing (TVD) formulation that accounts for thermal and chemical nonequilibrium effects. The stiffness due to the disparity in time scales is reduced by introducing a precondition matrix that allows a pointwise implicit solution of the source terms. Applications of the model to compute viscous hypersonic flows over a wedge and a cylinder showed that the postshock temperature plays a fundamental role in the achievement of thermal equilibrium and that the boundary layer is the most affected by thermal nonequilibrium. The flow field around a GK75-06-12 airfoil is analyzed by solving the two-dimensional compressible Navier-Stokes equations. The calculation was carried out, under the condition of Reynolds number 6 x 10(exp 6) and 2 x 10(exp 7), in each case CL (lift coefficient) was adjusted to 0.63. Author

AERODYNAMIC CHARACTERISTICS ANALYSIS OF GARABEDIAN-KORN 75-06-12 AIRFOIL: COMPUTATION USING q-OMEGA 2 EQUATION TURBULENCE MODEL

Eiji Shima and Kouichi Egami *In* NAL, Proceedings of the 10th NAL Symposium on Aircraft Computational Aerodynamics: CFD Workshop on GK Airfoil and ONERA M5 Geometry Mar. 1993 p 9-10 In JAPANESE (For primary document see N94-10466 01-02)
(Paper-2D-4) Avail: CASI HC A01/MF A02

Reynolds-averaged Navier-Stokes equations for perfect gas are solved numerically for flow around GK75-06-12 airfoil at the design conditions. Coakley's 2 equation turbulence model is used. In order to solve the q-omega equations stably some improvements are added to the numerical scheme. Two turbulence models, the q-omega model in this paper, and the Baldwin-Lomax model in another paper, are used for this workshop, then some characteristics of each solutions are compared. It is found that (1) surface pressure distributions are almost identical; and (2) q-omega solution has larger skin friction that B-L solution and that causes thicker boundary layer and bigger drag. The effect of the difference of initial and boundary conditions of q and omega variables are shown.

AERODYNAMIC CHARACTERISTICS ANALYSIS OF GARABEDIAN-KORN 75-06-12 AIRFOILS: COMPUTATION USING BALDWIN-LOMAX TURBULENCE MODEL
Eiji Shima and Kouichi Egami *In* NAL, Proceedings of the 10th NAL Symposium on Aircraft Computational Aerodynamics: CFD Workshop on GK Airfoil and ONERA M5 Geometry Mar. 1993 p 11-12 In JAPANESE (For primary document see N94-10466 01-02)
(Paper-2D-5) Avail: CASI HC A01/MF A02

Flow around a Garabedian-Korn 75-06-12 Airfoil is simulated numerically using Navier-Stokes equations. Baldwin-Lomax's algebraic turbulence model is adopted, but wake modeling is not used because it was shown by the previous investigation that turbulence viscosity in wake region has only little influence on pressure distribution and boundary layer characteristics. The equations are computed by the cell centered finite volume method using an implicit upwind scheme. C-type grid, which is generated algebraicly by the transfinite interpolation, is used. The large linear equations arising from the implicit scheme are solved approximately using the multi-color Gauss-Seidel method. Numerical experiments show that optimum inner iteration for rapid convergence is about 10. Author (revised)

The parametric study of Navier-Stokes computations has been performed to find an angle of attack which realizes a shockless pressure distribution over the Garabedian-Korn airfoil under the Mach number of 0.75. It would be almost impossible to realize a shockless solution by Navier-Stokes equations because of the viscous effect. A pressure distribution with weak shock has been attained, and it agrees with the theoretical pressure distribution quite well except in close vicinity to the location of a shock wave. In addition, a comparison has been made between computations using two different turbulence models. Author (revised)

A compendium of results of the 2D problem 'Garabedian-Korn Airfoil' is given. All of the submitted computation results were plotted on the respective figures to see the differences. Problem A: Design Point Computation was discussed significantly. Although pressure distribution gives fairly good agreement, turbulent boundary layer characteristics along chord, velocity profiles and eddy viscosity coefficient distributions in the boundary layer and wake disclosed scattered variation. The factors leading to the present results were discussed along with required future improvements.

DESCRIPTION OF 3D PROBLEM: FLOW ANALYSIS AROUND ONERA MODEL M5 CONFIGURATION
Jiro Nakamichi *In its* Proceedings of the 10th NAL Symposium on Aircraft Computational Aerodynamics: CFD Workshop on GK Airfoil and ONERA M5 Geometry Mar. 1993 p 57-61 In JAPANESE (For primary document see N94-10466 01-02)
Avail: CASI HC A01/MF A02

A description of the 3D Problem and Sub-problems A, B and C concerning flow analysis around the ONERA M5 configuration is presented. Problem A is to compute the flow at freestream conditions of Mach number 0.84, Reynolds number 1 x 10(exp 6), and angle of attack alpha = -1 degrees, with free transition condition. Problem B is to compute the flow at freestream conditions of Mach number 0.84, Reynolds number 6 x 10(exp 7), and angle of attack alpha = -1 degree with full turbulence condition. Problem C is to compute the aerodynamic characteristics of the model at freestream conditions of Mach number 0.84, Reynolds number 2 x 10(exp 6), and angles of attack, alpha = -3 degrees, -2 degrees and -1 degree, and to make plots of C(sub L)-alpha, C(sub L)-C(sub D) and C(sub L)-C(sub M) curves. The output formats are specified for all computed results.

Numerical simulation of transonic flow around the ONERA model M5 configuration have been carried out by solving Navier-Stokes equations. The numerical grid used in this analysis is generated by an algebraic method with a multi-block transformation. The grid generation around the given configuration consists of more than 5 million points. We adopt as governing equations Reynolds-averaged thin-layer approximate Navier-Stokes equations with a q-omega two equation turbulence model for a turbulent viscous flow. These equations are solved by an implicit finite volume TVD upwind scheme with Roe's approximate Riemann solver to estimate convective fluxes. Author (revised)

In the present method, boundary layer thickening is combined with laminar flow control to reduce drag. An aerodynamic body is accelerated enabling a ram turbine on the body to receive air at velocity V sub 0. The discharge air is directed over an aft portion of the aerodynamic body producing boundary layer thickening. The ram turbine also drives a compressor by applying torque to a shaft connected between the ram turbine and the compressor. The compressor sucks in lower boundary layer air through inlets in the shell of the aircraft producing laminar flow control and reducing drag. The discharge from the compressor is expanded in a nozzle to produce thrust. Official Gazette of the U.S. Patent and Trademark Office

A vortex attenuation device is presented which dissipates a lift-induced vortex generated by a lifting aircraft wing. The device consists of a positive pressure gradient producing means in the form of a compression panel attached to the lower surface of the wing and facing perpendicular to the airflow across the wing. The panel is located between the midpoint of the local wing cord and the trailing edge in the chord-wise direction and at a point which is approximately 55 percent of the wing span as measured from the fuselage center line in the spanwise direction. When deployed in flight, this panel produces a positive pressure gradient aligned with the final roll-up of the total vortex system which interrupts the axial flow in the vortex core and causes the vortex to collapse. STATIC INTERNAL PERFORMANCE OF A SINGLE EXPANSION RAMP NOZZLE WITH MULTIAXIS THRUST VECTORING CAPABILITY

Francis J. Capone and Alberto W. Schirmer (George Washington Univ., Hampton, VA.) Washington Jul. 1993 272 p
(RTOP 505-62-30-01)
(NASA-TM-4450; L-17163; NAS 1.15:4450) Avail: CASI HC A12/MF A03

An investigation was conducted at static conditions in order to determine the internal performance characteristics of a multiaxis thrust vectoring single expansion ramp nozzle. Yaw vectoring was achieved by deflecting yaw flaps in the nozzle sidewall into the nozzle exhaust flow. In order to eliminate any physical interference between the variable angle yaw flap deflected into the exhaust flow and the nozzle upper ramp and lower flap which were deflected for pitch vectoring, the downstream corners of both the nozzle ramp and lower flap were cut off to allow for up to 30 deg of yaw vectoring. The effects of nozzle upper ramp and lower flap cutout, yaw flap hinge line location and hinge inclination angle, sidewall containment, geometric pitch vector angle, and geometric yaw vector angle were studied. This investigation was conducted in the static-test facility of the Langley 16-Foot Transonic Tunnel at nozzle pressure ratios up to 8.0.

(NASA-TM-4500; H-1912; NAS 1.15:4500) Avail: CASI HC A03/MF A01

The Space Shuttle Orbiter has provided unique and important information on aircraft flight dynamics. This information has provided the opportunity to assess the flight-derived stability and control derivatives for maneuvering flight in the hypersonic regime. In the case of the Space Shuttle Orbiter, these derivatives are required to determine if certain configuration placards (limitations on the flight envelope) can be modified. These placards were determined on the basis of preflight predictions and the associated uncertainties. As flight-determined derivatives are obtained, the placards are reassessed, and some of them are removed or modified. Extraction of the stability and control derivatives was justified by operational considerations and not by research considerations. Using flight results to update the predicted database of the orbiter is one of the most completely documented processes for a flight vehicle. This process followed from the requirement for analysis of flight data for control system updates and for expansion of the operational flight envelope. These results show significant changes in many important stability and control derivatives from the preflight database. This paper presents some of the stability and control derivative results obtained from Space Shuttle flights. Some of the limitations of this information are also examined. Author

NAVIER-STOKES FLOWFIELD COMPUTATION OF WING/ROTOR INTERACTION FOR A TILT ROTOR AIRCRAFT IN HOVER
Ian G. Fejtek Jul. 1993 156 p
(Contract NCC2-55)
(NASA-CR-4532; A-93096; NAS 1.26:4532) Avail: CASI HC A08/MF A02

The download on the wing produced by the rotor-induced downwash of a tilt rotor aircraft in hover is of major concern because of its severe impact on payload-carrying capability. A method has been developed to help gain a better understanding of the fundamental fluid dynamics that causes this download, and to help find ways to reduce it. In particular, the method is employed in this work to analyze the effect of a tangential leading edge circulation-control jet on download reduction. Because of the complexities associated with modeling the complete configuration, this work focuses specifically on the wing/rotor interaction of a tilt rotor aircraft in hover. The three-dimensional, unsteady, thin-layer compressible Navier-Stokes equations are solved using a time-accurate, implicit, finite difference scheme that employs LU-ADI factorization. The rotor is modeled as an actuator disk which imparts both a radical and an azimuthal distribution of pressure rise and swirl to the flowfield. A momentum theory blade element analysis of the rotor is incorporated into the Navier-Stokes solution method. Solution blanking at interior points of the mesh has been shown here to be an effective technique in introducing the effects of the rotor and tangential leading edge jet. Results are presented both for a rotor alone and for wing/rotor interaction. The overall mean characteristics of the rotor flowfield are computed including the flow acceleration through the rotor disk, the axial and swirl velocities in the rotor downwash, and the slipstream contraction. Many of the complex tilt rotor flow features are captured including the highly three-dimensional flow over the wing, the recirculation fountain at the plane of symmetry, wing leading and trailing edge separation, and the large region of separated flow beneath the wing. Mean wing surface pressures compare fairly well with available experimental data, but the time-averaged download/thrust ratio is 20-30 percent higher than the measured value. The discrepancy is due to a combination of factors that are discussed. Leading edge tangential blowing, of constant strength along the wing span, is shown to be effective in reducing download. The jet serves primarily to reduce the pressure on the wing upper surface. The computation clearly shows that, because of the three-dimensionality of the flowfield, optimum blowing would involve a spanwise variation in blowing strength. Author

SPACE SHUTTLE HYPERSONIC AERODYNAMIC AND AEROTHERMODYNAMIC FLIGHT RESEARCH AND THE COMPARISON TO GROUND TEST RESULTS
Kenneth W. Iliff and Mary F. Shafer Jun. 1993 29 p Presented at the 17th Aerospace Ground Testing Conference, Nashville, TN, 6-8 Jul. 1992 Previously announced in IAA as A92-56812
(RTOP 506-69-50)
(NASA-TM-4499; H-1894; NAS 1.15:4499; AIAA Paper 92-3988) Avail: CASI HC A03/MF A01

Aerodynamic and aerothermodynamic comparisons between flight and ground test for the Space Shuttle at hypersonic speeds are discussed. All of the comparisons are taken from papers published by researchers active in the Space Shuttle program. The aerodynamic comparisons include stability and control derivatives, center-of-pressure location, and reaction control jet interaction. Comparisons are also discussed for various forms of heating, including catalytic, boundary layer, top centerline, side fuselage, OMS pod, wing leading edge, and shock interaction. The jet interaction and center-of-pressure location flight values exceeded not only the predictions but also the uncertainties of the predictions. Predictions were significantly exceeded for the heating caused by the vortex impingement on the OMS pods and for heating caused by the wing leading-edge shock interaction.

Direct and inverse problem solutions for an aerofoil are used for contrastive purposes, i.e., direct problems analyze flow around an aerofoil whose shape is prescribed, whereas inverse problems determine the aerofoil shape which realizes prescribed (and usually, idealized) flow conditions around it. In the present study, the solution of the inverse problem is applied differently because the flow input was measured in a wind tunnel experiment rather than being idealized. Investigation of the resultant aerofoil shape provided useful information on the real viscous flow characteristics around the aerofoil as well as on the feature of direct problem solution method to analyze it. The aerofoil shape from the inverse problem solution was found to be thicker than that of the one installed in the wind tunnel, with its trailing edge open. This difference is due to the boundary layer around the wind tunnel aerofoil, since inviscid flow was assumed in the computation and the actual fluid in the wind tunnel was viscous. The additional thickness of the converged aerofoil is of the same order as the displacement thickness of the boundary layer, hence, demonstrating the reliability of the popular approach to incorporate viscous effects into the inviscid analysis by solving the direct problem for an aerofoil with its shape modified by adding the displacement thickness of the boundary layer to the original shape. Inviscid flow analysis around the output shape showed that the applied inverse problem solution was quite accurate when the Reynolds number was 1.0 x 10(exp 5). Author (NASDA)

LASER VELOCIMETER MEASUREMENTS OF THE FLOW FIELD GENERATED BY A FORWARD-SWEPT PROPFAN DURING FLUTTER

Gary G. Podboy and Martin J. Krupar Jul. 1993 34 p Presented at the 24th AIAA Fluid Dynamics Conference, Orlando, FL, 6-9 Jul. 1993 Original contains color illustrations
(RTOP 535-03-10)
(NASA-TM-106195; E-7903; NAS 1.15:106195; AIAA Paper 93-2919)
Avail: CASI HC A03/MF A01; 12 functional color pages

Results are presented from an investigation to measure the flow field generated by a forward-swept propfan operating in flutter at a low forward velocity. For comparison to the flutter condition, flow field data are also presented for a slightly reduced rotational speed just below flutter. The forward-swept propfan was tested as the front rotor of a counterrotating pusher propeller. A laser Doppler velocimeter (LDV) was used to measure the velocity field in planes normal to the model centerline downstream of the rotor and in planes of constant radius within the blade passages at each operating condition. A comparison of the data taken at the two different operating conditions indicated that the mean, time-averaged flow about the blades did not change drastically as the propfan rotational speed was increased from the stable operating point to the flutter condition. No regions of flow separation could be identified in the data plots of the mean intrablade flow field. The data also indicate that the relative flow about the blades remained subsonic during flutter operation. The blades were found to have a higher than expected tip loading at both operating conditions. This is thought to have been caused by the outer blade sections twisting under load to higher than expected effective blade angles. This high tip loading resulted in strong vortices and a very nonuniform flow downstream of the tips of the forward-swept blades. This high tip loading may also have caused the blade flutter. Author

PARACHUTE HAVING IMPROVED VENT LINE STACKING Patent Application.

John E. Hengel 29 Mar. 1993 12 p
(NASA-Case-MFS-28508-1; NAS 1.71:MFS-28508-1; US-Patent-Appl-SN-037877) Avail: CASI HC A03/MF A01

A parachute having an improved vent line stacking wherein the parachute is provided with a canopy having a central vent opening and a vent band secured to the canopy around the periphery of the vent opening, with a plurality of vent lines each lying on a diameter of the vent opening and having its ends secured to the vent band on opposite sides of the vent opening is described. The vent lines are sewed to the vent band in an order such that the end of a first vent line is sewed to the vent band at a starting point with the end of a second vent band then being sewed to the vent band adjacent to and counterclockwise from the first band. A third vent band is sewed to the vent band adjacent to and clockwise from the first band, with a fourth vent band being sewed to the vent band adjacent to and counterclockwise from the second vent band. It can be seen that, if the vent lines are numbered in the order of being sewed to the vent band, the odd numbered vent lines will run consecutively in a clockwise direction and the even numbered lines will run consecutively in a counterclockwise direction from the starting point. With this order of assembly, each and every vent line will be separated from adjacent vent lines by no more than one vent line in the center of the vent opening where the vent lines cross. THE EFFECTS OF SUCCESSIVE DISTORTIONS ON A TURBULENT BOUNDARY LAYER IN A SUPERSONIC FLOW Ph.D. Thesis

Douglas Robert Smith 1993 231 p
Avail: Univ. Microfilms Order No. DA9311228

Four experiments which investigate the effects of strong distortions on a supersonic turbulent boundary layer (Ma = 2.89, Re(sub theta) is approximately 80000) are discussed. The first two experiments include a boundary layer flow on a flat wall experiencing a pressure rise equivalent to 16 degrees of turning (Flat Plate Model 4), and a boundary layer flow encountering a 20 degrees expansion corner. In the first experiment, the pressure gradient matches the gradient on Donovans Model 4 curved wall (delta(sub 0)/R equals 0.08). In the second experiment, the nature of the expanded flow permits a calculation of the turbulence based upon Rapid Distortion Approximations. The second two experiments are an intensive study of the boundary layer response to successive distortions. In these two flows, the boundary layer experiences successive applications of compression and expansion on two forward-facing ramps with 20 degrees of turning. The first two studies investigate the influence of streamline curvature and pressure gradients on a supersonic turbulent boundary layer and demonstrate that compressibility effects arising from the pressure gradient dominate the flow response. The effect of curvature is small but not negligible. In the expansion corner flow, the evolution of the turbulence fields in the distortion is predicted surprisingly well with Rapid Distortion Approximations. The measurements in the compression-expansion flows provide some remarkable insight into the relaxation behavior of a strongly distorted boundary layer. In the middle of the relaxing boundary layer downstream of the distortions, the turbulence exhibits a second-order response, while near the boundary layer edge the response is first-order. The turbulent shear stress collapses throughout most of the boundary layer, and an overall destruction of the turbulence production mechanisms is apparent as the boundary layer exhibits a slow recovery.

EXAMINATION OF WALL FUNCTIONS FOR A PARABOLIZED NAVIER-STOKES CODE FOR SUPERSONIC FLOW

T. H. Alsbrooks (New Mexico Univ., Albuquerque.) 1993 17 p Presented at the AIAA Region 4 Student Conference, Houston, TX, 1-3 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011590; SAND-93-0878C; CONF-9304118-1) Avail: CASI HC A03/MF A01

Solutions from a Parabolized Navier-Stokes (PNS) code with an algebraic turbulence model are compared with wall functions. The wall functions represent the turbulent flow profiles in the viscous sublayer, thus removing many grid points from the solution procedure. The wall functions are intended to replace the computed profiles between the body surface and a match point in the logarithmic region. A supersonic adiabatic flow case was examined first. This adiabatic case indicates close agreement between computed velocity profiles near the wall and the wall function for a limited range of suitable match points in the logarithmic region. In an attempt to improve marching stability, a laminar to turbulent transition routine was implemented at the start of the PNS code. Implementing the wall function with the transitional routine in the PNS code is expected to reduce computational time while maintaining good accuracy in computed skin friction. DOE

LASER ANEMOMETER MEASUREMENTS AND COMPUTATIONS FOR TRANSONIC FLOW CONDITIONS IN AN ANNULAR CASCADE OF HIGH TURNING CORE TURBINE VANES

Louis J. Goldman Washington Jul. 1993 33 p

(RTOP 505-62-52)

(NASA-TP-3383; E-7662; NAS 1.60:3383) Avail: CASI HC A03/MF A01

An advanced laser anemometer (LA) was used to measure the axial and tangential velocity components in an annular cascade of turbine stator vanes operating at transonic flow conditions. The vanes tested were based on a previous redesign of the first-stage stator in a two-stage turbine for a high-bypass-ratio engine. The vanes produced 75 deg of flow turning. Tests were conducted on a 0.771-scale model of the engine-sized stator. The advanced LA fringe system employed an extremely small 50-micron diameter probe volume. Window correction optics were used to ensure that the laser beams did not uncross in passing through the curved optical access port. Experimental LA measurements of velocity and turbulence were obtained at the mean radius upstream of, within, and downstream of the stator vane row at an exit critical velocity ratio of 1.050 at the hub. Static pressures were also measured on the vane surface. The measurements are compared, where possible, with calculations from a three-dimensional inviscid flow analysis. Comparisons were also made with the results obtained previously when these same vanes were tested at the design exit critical velocity ratio of 0.896 at the hub. The data are presented in both graphical and tabulated form so that they can be readily compared against other turbomachinery computations. Author (revised)

WALL INTERFERENCE CORRECTION BASED ON INTERFACE MEASUREMENTS IN SUBSONIC WIND TUNNEL TESTING Ph.D. Thesis

Norbert Manfred Herm Ulbrich 1992 163 p

Avail: Univ. Microfilms Order No. DA9306700

Two types of wall interference correction methods in subsonic wind tunnel testing are investigated which are based on interface measurements of velocities or pressures in the flow field. The first method, called Two-Interface method, is derived from a small perturbation solution of the two-dimensional potential equation in subsonic flow. A surface pressure coefficient and angle of attack correction is calculated using axial velocity measurements on the first interface and vertical velocity measurements on the second interface in the wind tunnel. The method only requires the measurement of axial velocities on the first interface, if the solid wall of a wind tunnel is selected as the second interface. The method is applied to available experimental data. Corrected surface pressure coefficients show reasonable agreement with test data recorded in unconfined flow. The second method, called Wall Signature method, can be used to determine wall interference corrections in three-dimensional incompressible wind tunnel testing. Modifications of the Wall Signature method are presented. Pressure measurements on a limited number of wall locations are combined with influence functions to obtain an equivalent body representation of the test article and its wake in terms of surface panel elements. Blockage corrections in a wind tunnel with non-rectangular cross-section are computed using this equivalent body description and an existing three-dimensional panel code. A direct comparison of equivalent body and test article geometry is possible. The analysis of the symmetric part of the wall signature is improved by introducing a least squares fit based on a Gaussian. Advantages and disadvantages of Two-Interface and Wall Signature method are compared. The Two-Interface method is applicable in subsonic wind tunnel testing as long as the small perturbation assumption holds. This method uses explicit equations to compute wall interference corrections which makes it suited for on-line operation. The modified Wall Signature method is not restricted to slender bodies and can even be applied to high angle of attack tests. In its present form, however, the modified Wall Signature method is only applicable in post-test analysis as the method is computationally intensive. Dissert. Abstr.

PHYSICS OF FOREBODY FLOW CONTROL

Gabriel I. Font Aug. 1993 45 p

(Contract NCC2-729)

(NASA-CR-193626; NAS 1.26:193626; MCAT-93-12) Avail: CASI HC A03/MF A01

Performance in the high angle of attack regime is required by many different types of aircraft. Military aircraft, such as fighters, utilize flight in this regime to improve maneuverability. Civilian aircraft, such as supersonic or hypersonic transports, will also need to operate in this regime during take off and landing, due to their small highly swept wings. Flight at high angles of attack is problematic due to the vortices being created on the nose of the aircraft. The vortices tend to become asymmetric and produce side forces. At the same time, the rudders are less effective because they are becoming immersed in the flow separating from the wings and fuselage. Consequently, the side force produced by the vortices on the nose tend to destabilize the aircraft. This situation may be corrected through the use of a forebody flow control system such as tangential slot blowing. In this concept, a jet is blown from the nose in an effort to alter the flow field around the nose and diminish the destabilizing side force. Alternately, the jet may be used to create a side force which could be used to augment the rudders. This would allow the size of the rudders to be decreased which would, in turn, diminish the cruise drag. Therefore, the use of a tangential slot blowing system has the potential for improving both the maneuver performance and the cruise performance of an aircraft. The present study was conducted to explore the physics of forebody flow control. The study consisted of two major thrusts: (1) exploration of forebody flow control with tangential slot blowing; (2) investigation of flow and field response to a general perturbation. Author

BLADING MODELS FOR TURBAN AND CSPAN TURBOMACHINE DESIGN CODES Final Report

Arthur J. Glassman Jul. 1993 9 p

(Grant NAG3-1165; RTOP 505-69-50)

(NASA-CR-191164; E-7997; NAS 1.26:191164) Avail: CASI HC A02/MF A01

Blading models added to TURBAN, an axial turbine meanline design code, and CSPAN, an axial compressor spanline design code, are presented. Calculations of blade chord length, blade axial length, and number of blades for each blade row are now provided by each code. In order to accomplish this, computational models for axial solidity and stagger angle were added to TURBAN. For a compressor, where solidity and chord were already available from input, the modeling additions to CSPAN were for stagger angle and for the blade angles to include incidence and deviation. All added computations utilized models already available in the literature. Author

NONLINEAR ASPECTS OF TRANSONIC AEROELASTICITY Thesis, 1992

Hema Sandhyarani Murty Jan. 1993 212 p

(UTIAS-RN-345) Copyright Avail: CASI HC A10/MF A03

Flutter analysis of airfoils in transonic flow has traditionally assumed linearity of the aerodynamic loads and moment with motion amplitude. However, the nonlinear nature of the mixed flow, incorporating large amplitude shock wave motion, may significantly invalidate the linearity assumption. In this thesis, the effect of nonlinear transonic aerodynamics on the flutter analysis is analyzed utilizing a simplified linear structural model. The aerodynamic conditions under which these effects are significant are determined for specific cases using the NACA 64A010 airfoil. In order to accurately determine the aerodynamic loads and moment, an unsteady full potential code was developed. This code was joined to an algorithm which integrates the structural equations of motion in time. A flutter analysis based on the assumption of linear aerodynamics was carried out to determine the neutral stability conditions defined by a set of structural and aerodynamic parameters. These neutral stability conditions were then used in the structural equations of motion with nonlinear aerodynamic loads and moment. These equations were then integrated in time to determine the response of the system. If the time response was not neutrally stable, then the structural parameter, mu, the airfoil-to-air mass ratio was varied until the time response was neutrally stable. If the difference in the value of the 'nonlinear'mu to 'linear' mu was greater than 10 percent, then that case was considered to exhibit significant nonlinearities. Author (revised)

COMPUTATION OF HYPERSONIC NOSETIP HEAT TRANSFER RATES FOR AN M829-LIKE PROJECTILE
Bernard J. Guidos and Walter B. Sturek Apr. 1993 28 p
(DA Proj. 1L1-62618-AH-80)
(AD-A263226; ARL-MR-52) Avail: CASI HC A03/MF A01

Computational predictions are presented of in-flight blunt nosetip heat transfer rates for an M829-like projectile configuration. Predictions are made for higher-than-conventional flight velocities up to 3 km/sec (Mach 8.8), for both laminar and turbulent flows. Comparisons are made between two predictive approaches: (1) a time-dependent Navier-Stokes numerical technique, and (2) a boundary-layer engineering analysis technique (known as ASCC). Additional comparison is made with wind-tunnel heat transfer measurements for a hemisphere-cylinder configuration at Mach 6.82. The Navier-Stokes predictions agree with the experimental data to within the estimated measurement accuracy. The comparisons between the two predictive approaches show agreement with 10 percent for laminar flow. For turbulent flow, the two codes agree within 10 percent at the stagnation point, and within about 30-40 percent further downstream. The heat transfer rates presented provide a boundary condition model for subsequent analysis of projectile transient thermal response. Author (revised)

THE MODELLING OF AERODYNAMIC FLOWS BY SOLUTION OF THE EULER EQUATIONS ON MIXED POLYHEDRAL GRIDS
A. J. Peace and J. A. Shaw Apr. 1992 44 p Previously announced in IAA as A93-21218
(Contract SLS41B/2437)
(ARA-84) Avail: CASI HC A03/MF A01

An algorithm for obtaining solutions to the compressible Euler equations on mixed polyhedral grids is described. These grids, which are in general composed of hexahedral, pentahedral, and tetrahedral elements are used in the modeling of aerodynamic flows over complex three-dimensional geometries. The hexahedra are grouped into regular blocks, while the other elements are part of irregular grid regions, giving rise to the term 'hybrid grid approach'. The interconnection of the grid elements is defined by an efficient data structure, which supplies the required information to drive the Euler algorithm. In fact, cell-vertex and cell-center spatial discretization variants of this algorithm are detailed, along with an explicit time-marching scheme for obtaining steady state solutions. Results on two geometrically simple configurations provide an evaluation of these solution techniques, while the focus on a third, complex configuration, demonstrates the potential of the method in addressing the flow over general aircraft geometries. UNSTEADY FLOW PAST A NACA 0012 AIRFOIL PITCHING AT CONSTANT RATES Final Report, 1 Nov. 1988 - 31 Oct. 1992
Luiz M. Lourenco, A. Krothapalli, L. VanDommelen, and C. Shih 13 Apr. 1993 82 p
(Contract F49629-89-C-0014)
(AD-A265159; FMRL-TR-8; AFOSR-93-0363TR) Avail: CASI HC A05/MF A01

The dynamic stall process of a NACA 0012 airfoil undergoing a constant-rate pitching-up motion is studied experimentally in a water towing tank facility. This study focuses on the detailed measurement of the unsteady separated flow in the vicinity of the leading and trailing edges of the airfoil. The measurements are carried out using the Particle Image Velocimetry (PIV) technique. This technique provides the two-dimensional velocity and associated vorticity fields, at various instants in time, in the mid-span of the airfoil. Near the leading edge, large vortical structures emerge as a consequence of Van Dommelen and Shen type separation and a local vorticity accumulation. The interaction of these vortices with the reversing boundary layer vorticity initiates a secondary flow separation and the formation of a secondary vortex. The mutual induction of this counter-rotating vortex pair eventually leads to the ejection process of the dynamic stall vortex from the leading edge region. DTIC

(Grant AF-AFOSR-0093-90)
(AD-A265626; AFOSR-93-0404TR) Avail: CASI HC A03/MF A01

The effort to use spectral methods to simulate flows with shock waves is summarized in four published papers. In one of the papers, the authors study uniform high order spectral methods to solve multi-dimensional Euler equations for gas dynamics. Uniform high order spectral approximations with spectral accuracy in smooth regions of solutions are constructed by introducing the idea of the Essentially Non-Oscillatory (ENO) polynomial interpolations into the spectral methods. Based on the new approximations, nonoscillatory spectral methods which possess the properties of both upwinding difference schemes and spectral methods were proposed. Numerical results are presented for the inviscid Burger's equation, and for one dimensional Euler equations including the interactions between a shock wave and density disturbance, Sod's and Lax's shock tube problems, and the blast wave problem. Finally, the interaction between a Mach 3 two dimensional shock wave and a rotating vortex is simulated. DTIC

A DETERMINATION OF THE EXTERNAL FORCES REQUIRED TO MOVE THE BENCHMARK ACTIVE CONTROLS TESTING MODEL IN PURE PLUNGE AND PURE PITCH
Jonathan DCruz Jul. 1993 31 p
(RTOP 505-63-50-15)
(NASA-TM-107743; NAS 1.15:107743) Avail: CASI HC A03/MF A01

In view of the strong need for a well-documented set of experimental data which is suitable for the validation and/or calibration of modern Computational Fluid Dynamics codes, the Benchmark Models Program was initiated by the Structural Dynamics Division of the NASA Langley Research Center. One of the models in the program, the Benchmark Active Controls Testing Model, consists of a rigid wing of rectangular planform with a NACA 0012 profile and three control surfaces (a trailing-edge control surface, a lower-surface spoiler, and an upper-surface spoiler). The model is affixed to a flexible mount system which allows only plunging and/or pitching motion. An approximate analytical determination of the forces required to move this model, with its control surfaces fixed, in pure plunge and pure pitch at a number of test conditions is included. This provides a good indication of the type of actuator system required to generate the aerodynamic data resulting from pure plunging and pure pitching motion, in which much interest was expressed. The analysis makes use of previously obtained numerical results. Author (revised)

NEW THERMOPLASTIC LAMINATING ADHESIVES FOR THE AIRCRAFT INDUSTRY WITH LOW HEAT RELEASE AND LOW SMOKE EMISSION c27
Sarfraz A. Siddiqui *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 13-20 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

In Aeroplas '90 and Fire Safety '91, the flammability behavior of several aircraft substrates with different types of decorative laminates were discussed. We concluded that due to the substrate's own fire characteristics, aircraft decorative laminate manufacturers have substantial problems meeting current Heat Release and Smoke Emission requirements. To solve this problem, we decided to develop new thermoplastic adhesives which will help decorative laminates manufacturers meet current Federal Aviation Administration (FAA) flammability requirements on virtually all substrates. These adhesive films are tested on commercially available thermoplastic decorative laminate with a PVF surface, after bonding to crushed core substrate. All flammability tests are carried out in FAA-approved OSU Heat Release and NBS Smoke Emission Chambers. Toxicity tests are also carried out using the same NBS Smoke Chamber. The flammability test data of these new adhesives are discussed. Author (revised)

Gillfoam was developed specifically to be a structural phenolic foam capable of providing increased cabin safety during a fire in an aircraft. This product meets current Federal Airworthiness Regulations pertaining to peak and total heat release, vertical and 45 deg flammability, smoke density, and toxic gas release. The NIST smoke density (D(sub s)) for the highest density foam (20 lbs/ft(sup 3)) is less than 50 when the product is tested in the flaming mode. Foams having densities ranging between 4.0 and 20.0 lbs/ft(sup 3) are currently being evaluated for a variety of potential applications. Some of these applications include: environmental control system (ECS) ducting; cores for partitions, bulkheads, and galley panels; and for close-outs in laminated honeycomb sidewall panels. Gillfoam, as sheet stock, is also conformable in crushed core applications so it can be laminated to produce contoured profiles. When fabricated into a duct, the low smoke foam product is lighter in weight than either a multi-layer prepreg duct or an aluminum duct of comparable size. Moreover, Gillfoam ducts may require no additional thermal insulation, depending on specific applications. Development issues, performance properties, and several applications of this state-of-the-art structural foam are described. Author (revised)

POLYIMIDE FOAM INSULATION SYSTEMS: A MAJOR WEIGHT REDUCTION AND IMPROVEMENT IN FIRE RESISTANCE OF SIDEWALL SYSTEMS c27
Michael D. ODonnell *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 29-35 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

As a result of the 1967 Apollo fire, NASA started the Fireman Program. NASA's requirements for materials were for the lowest possible smoke, flame spread, toxicity, off-gassing, and out-gassing. The final NASA requirement was that weight should not exceed that of the existing materials. This resulted in the full development of polyimide foam. Solimide polyimide foam exceeds all of the stated requirements including weight, which is up to five times lighter in some applications than the materials it replaces. Commercial aircraft is a different situation. Today there are very limited fire requirements on insulation materials, or any material outside those requiring the O.S.U. Heat Release and Furnace Burners. However, there are several potential changes in requirements that would effect insulation in the future: (1) expansion of the fire test requirements such as O.S.U. Heat Release, Smoke Generation, etc. to include all non-metallic materials, structures, and systems from the skin in-board throughout the entire interior; and (2) burn-through requirements as discussed by the CAA and their proposed test and fire hardening of aircraft being developed by Darchem Engineering, Ltd. Additional testing or improved fire hardening has usually been considered as costly and unnecessary relative to benefits derived. Author (revised)

A REPAIR PATCHING SYSTEM FOR AIRCRAFT CARGO LINERS
Douglas F. Smith and Melvin R. Kantz *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 49-54 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

With the FAA's mandate that cargo liner repair patches must meet flame penetration requirements described in FAR 25, Appendix F, Part 3, several new repair systems were introduced to the airlines to meet this demanding application. Previously available patches consisted of liner material with a pressure sensitive adhesive. While easy to use, the adhesive could not withstand temperatures to 1800 F, as required by the flame penetration test. Consequently, the patch fell from the liner, allowing the flame to penetrate the damaged area. The currently available repair systems were developed to meet the flame penetration requirements; however, the patches are difficult and time-consuming to apply. Moreover, they are expensive. A new patching system was developed which can be applied in less than 5 minutes, depending on the extent of the damage. This system is designated Gillpatch 2 and meets all flammability and flame penetration resistance tests described in FAR 25.855. The patch and adhesive combinations will be available in kits for rapid, on-the-spot repairs. The installation criteria and technical approach to solving the repair patch needs of the airlines and maintenance stations are described. Author (revised)

PRIMASET (TM): A SAFER MATERIAL FOR AIRCRAFT INTERIOR APPLICATIONS
Sajal Das *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 55-65 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Aircraft interior designers favor plastics for their low weight, decorative effect, and functional strength. However, many plastics tend to emit smoke and toxic gases when they burn. Organic compounds such as hydrogen cyanide, hydrochloric acid, sulfur dioxide, carbon monoxide, and various oxides of nitrogen can be part of the lethal gaseous cocktail that modern laminates produce on combustion. Following a number of highly publicized accidents in which fatalities were primarily caused by fire on the ground, the Federal Aviation Administration (FAA) has moved to upgrade the fire performance of aircraft interiors, focusing on flammability. Faced with public horror and outrage over the years, airworthiness authorities have sought to make cabin interiors safer in fire. The underlying philosophy is simple: all concerned accept that, once established, a fire is likely to destroy the aircraft, but if the fire can be contained for a brief period, the occupants will be given time to evacuate. The realistic brief period has been determined to be two to five minutes in most of the Fire, Smoke, and Toxicity (FST) tests. A new non-volatile cure thermoset (Primaset) resin and some of its inherently good FST characteristics are discussed. In addition, a comparative study of cure characteristics of phenolic-triazine (PT) resin and phenol-formaldehyde (PF) resin is discussed. Author (revised)

A NEW FR WATER RESISTANT ACOUSTIC INSULATION MATERIAL FOR AIRCRAFT c24
Novis Smith and Geoff Gould *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 67-84 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

A new lightweight fire resistant thermal and acoustical insulation material was developed for weight critical applications such as aircraft. This new insulation is based on non melting microfibers of heat treated oxidized polyacrylonitrile fiber (OPF). The insulation material is in the form of light weight battings in the range of 0.2 to 0.4 lbs/ft. This material (Curlon) has outstanding fire blocking properties with an LOI of 58, nonconducting, high emissivity, and nonmelting. The flame burn through resistance of these battings significantly exceeds that of glass and polyimide insulation materials at 2000 F. The thermal, acoustical, and fire resistant properties of this new insulation are presented. Author (revised)

NEW TECHNOLOGY FOR EFFECTIVE CONTROL OF FLAMMABILITY IN POLYOLEFIN FIBER/TEXTILES c27
Charles W. Yacomeni *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 85-91 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

The unsolved issue of how to effectively flame retard polyolefin (in particular polypropylene) fiber in order to impart inherent flame resistance to a finished textile is addressed. One product is used in substantial quantities world-wide to flame retard textiles (e.g. automotive and commercial upholstery) traditionally made from polyamide or polyester fiber; this product is applied in the form of a compounded latex back-coating. Polypropylene is difficult to flame retard. Substantial efforts have been made to incorporate some of the previously mentioned products into polypropylene fiber during the fiber extrusion process with some limited success. However most of these products are not melt blendable with polypropylene and therefore particle size of the flame retardant becomes a critical issue at the lower fiber deniers. There is also the necessity of antimony trioxide as a synergist which represents yet another incompatible particle present in the fiber cross section. Migration of an incompatible flame retardant to the fiber surface is also a possibility which could cause build-up on fiber processing equipment. Before discussion of flammability test results, it is appropriate to review the technical barriers that had to be overcome in order to offer a commercially viable product. The following issues had to be evaluated: spinnability, UV stability, corrosion, odor, coloration, and flammability. Each of these issues is addressed. Derived from text

APPLICATIONS OF CONTINUOUS FIBER REINFORCED THERMOPLASTICS IN AIRCRAFT INTERIORS c27
Robert G. Diehl *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 93-104 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

As part of a technology development program, actual aircraft interior parts were manufactured from polyetherimide (PEI) resin reinforced with woven glass fiber in the form of composite solid laminates and sandwich materials. These parts are evaluated against an aircraft manufacturer's design criteria, highlighting critical areas. The status of a number of the parts is given - technology proving, flying prototype part, serial production, etc. The materials have good fire safety properties, some unexpected mechanical properties, and an above average contribution to parts cost. The state of the art is such that the present interior applications for this material are restricted to areas with highly specific requirements. Further development to improve some mechanical properties and process control could quickly open up the field because of substantial savings in manufacturing costs. Author (revised)

ADVANCED PHENOLIC SYSTEMS FOR AIRCRAFT INTERIORS c27
Herman Gupta and Mickey McCabe *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 105-119 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Recent advances in the phenolic prepreg systems suitable for aircraft interior's applications are described. The current state of the art phenolic systems achieve a balance of properties and comfortably meet heat release and smoke emission requirements of various regulatory agencies such as FAR 25.853 and ATS 1000.001. A recent commercially available phenol formaldehyde resin based prepreg product SPH 2400 is reviewed. A single ply SPH 2400 sandwich laminates fabricated from Nomex honeycomb core and 7781 style fiberglass show Ohio State University (OSU) test peak heat release characteristics as low as 18 KW/M(sup 2) and an average OSU heat release of 15 KW-Min/M(sup 2) over a period of two minutes. The optical density of smoke emission measured by NBS method in naming mode was found to be only 6 when measured over four minutes. The product SPH 2400 can be processed by using a variety of techniques such as vacuum bag molding, multiple opening press (MOP) molding, and crushed core (CC) press molding. The prepreg system possesses outstanding self adhesive characteristics to a variety of core substrate and does not require an additional adhesive layer for core bonding. A proprietary latent catalysis technology enables rapid cures at temperature as low as 132 C (270 F) while maintaining excellent out time at room temperature. Author (revised)

URALANE (TM) 5774-A/B: CIBA-GEIGY'S ADVANCED URETHANE ADHESIVE FOR THE AIRCRAFT INDUSTRY c27
Edwin C. Clark and Jose Salazar *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 121-135 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

In the aircraft industry, several trends in the fabrication of aircraft interiors have been observed in recent years. One development has been the application of new, flame resistant thermoplastics (i.e. Declar-T, Ultem, Kydex, Europlex, Radel, etc.) to the construction of aircraft interiors. Use of these advanced materials by aircraft manufacturers has created an accompanying need for new adhesives that can effectively bond the tough-to-join thermoplastics and also provide the required flame, smoke, and toxicity (FST) performance. In addition to these materials trends, is a heightened industry awareness of worker safety and the importance of minimizing worker exposure to chemicals. In response to industry demands generated by the above-mentioned factors, CIBA-GEIGY Corporation's Furane Aerospace Product Group initiated a new product development effort several years ago. The program was aimed at formulating an effective thermoplastic bonding adhesive that could be supplied in an environmentally improved package. The result was the creation of Uralane 5774-A/B urethane adhesive. Uralane 5774-A/B is a two-component urethane adhesive designed to bond the advanced thermoplastics used in fabricating aircraft interior components. The adhesive complies with the FST requirements of FAR 25.853 a. And, it is formulated with a 2 to 1 mix ratio by volume, permitting packaging in Accumix dual barrel cartridge kits. The kits are designed to accurately store, mix, and dispense Uralane 5774-A/B without the need for direct worker exposure to the adhesive. An additional safety benefit of Uralane 5774-A/B is that it can be applied to unabraded substrates and requires only minimal surface preparation, thereby reducing worker exposure to dust and harsh solvents. Several major airframe manufacturers, aircraft interior fabricators, and airlines have now specified this new adhesive for use in their shops. It is the intent to highlight the features and benefits of Uralane 5774-A/B as they apply to the aircraft industry. Author (revised)

THE FIRE PROPERTIES OF INSULATION BAGS, AS INSTALLED AND AFTER AIRCRAFT OPERATIONS **c27**

Robert F. Davis *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 137-143 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

Polymeric films and insulation bag materials made from these films were exposed to hydrolysis conditions and subjected to the 12 second Vertical Bunsen Burner Test. Despite a major weakening in mechanical strength of the polyester film samples, all the samples passed the test by shrinking away from the flame, immediately. Only by testing the samples in multiple layers were slight differences observed. Instead of developing a suitable accelerated aging program, it is recommended that the industry test used insulation bags when they are replaced during maintenance schedules, because the instability of polyester based materials may still be of concern. COMPUTER-AIDED MOLECULAR DESIGN OF FIRE RESISTANT AIRCRAFT MATERIALS **c24**

Marc R. Nyden and James E. Brown *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 147-158 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Molecular dynamic simulations and Cone Calorimeter measurements were used to assess the effects of electron beam irradiation and heat treatments on the flammability of the honeycomb composites used in the sidewalls, ceilings, and stowage bins of commercial aircraft. The irradiation of this material did not result in any measureable changes. A dramatic reduction in the peak rate of heat release, however, was observed in samples that had been heated overnight at 250 C. Author (revised)

FIRE-RESISTANT HYDROLYTICALLY STABLE POLY(ARYLENE PHOSPHINE OXIDE) MATERIAL SYSTEMS **c27**

C. D. Smith, H. J. Grubbs, A. Gungor, J. Wescott, S. C. Liptak, P. A. Wood, and James E. McGrath *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 159-174 Sponsored by NSF (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Arylene ether phosphine oxide homopolymers were prepared via nucleophilic aromatic substitution step polymerization of bis (4-fluorophenyl)phenyl phosphine oxide (1) with various aromatic bisphenols in the presence of a weak base and an aprotic dipolar solvent. These thermoplastic materials with T(sub g) values in the range of about 200-285 C showed 5 percent weight loss in air around 500 C with substantial amounts (40-70 percent) of char yield at 700 C, in air, which suggests excellent self-extinguishing characteristics relative to other engineering thermoplastics. Additionally, the presence of high content phosphorus in the char after such high heating further implied a possible condensed phase mechanism. Nucleophilic substitution of (1) with m-aminophenyl oxide afforded the diamine, which was a key intermediate for thermoplastic polyimides, epoxy- and bismaleimide networks. These systems also showed extremely low amounts of etching in oxygen plasma when compared to other engineering polymers. The presence of phosphorus residues after either burning or etching with oxygen plasma suggests applications of commercial importance, including fire resistant materials. Qualitative burning experiments supports these conclusions. Author (revised)

A NON-HALOGENATED, FLAME RETARDED POLYCARBONATE **c27**

Takashi Kashiwagi, Thomas G. Cleary, Gary C. Davis (General Electric Co., Schenectady, NY.), and John H. Lupinski (General Electric Co., Schenectady, NY.) *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 175-189 Sponsored by GE (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Various flammability properties of a siloxane-containing bisphenol-A polycarbonate sample, with the siloxane as an additive or as a copolymer, were measured and compared with those of a pure polycarbonate sample. The results show that the peak heat release rate for the siloxane-containing polycarbonate sample is significantly reduced (less than half) compared to that for the pure polycarbonate sample with two different sizes of sample, 10cm x 10cm and 40cm x 40cm. However, the ignition delay time for the siloxane-containing sample is shorter than that for the pure polycarbonate sample. Also, the flame spread rate under an external radiant flux becomes faster for the siloxane-containing sample than that for the pure polycarbonate sample. The observed char behavior, such as char depth, physical nature and apparent combustibility, and its impact on flammability properties are discussed. Author (revised)

AN INVESTIGATION INTO AIRCRAFT FUSELAGE FIRE HARDENING

Cliff T. M. Hall and Mark Snell *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 191-205 Sponsored by Civil Aviation Authority (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

The current investigation into the development of a new test facility which can reproduce in a controlled manner the fire conditions that would be experienced by an aircraft fuselage following a fuel spillage incident is outlined. The early investigation work has led to the definition of a fire source based upon previous test work in the aircraft industry and industrial pool fires in general. This definition was then used to design a test facility which was built and commissioned. It can create a reproducible thermal insult of up to 1150 C and 210 Kw/m(sup 2). The commissioning program is now complete, however, one particular aspect proved to be of great interest. That is the increased burnthrough rate due to soot deposition during the first few seconds of a pool fire. This phenomena will prove to be very critical as the ultimate aim of the project is to enhance the burnthrough capabilities of aircraft fuselages. The program will look at the determination of burnthrough times of existing fuselages before moving onto investigating the burnthrough capabilities of both improved materials and systems. APPLICATIONS OF A MODEL TO PREDICT FLAME SPREAD OVER INTERIOR FINISH MATERIALS IN A COMPARTMENT **c25**

James G. Quintiere, Gerald Haynes, and Brian T. Rhodes *In* FAA, Proceedings of the International Conference for the Promotion of Advanced

Fire Resistant Aircraft Interior Materials Mar. 1993 p 207-224 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Results from a mathematical model are investigated for fire growth on wall and ceiling combustible interior finish material in a compartment. A corner fire ignition source is maintained for 10 minutes at 100 kW and subsequently increased to 300 kW. For this scenario experimental results are available from the EURIFIC program, and are compared to the model. The time for the total rate of energy release rate to reach 1 MW is examined. In addition to the 11 EURIFIC materials, eight other materials are examined in this scenario by using the model. These materials represent the type of materials formerly and currently used as cabin interior finish materials in commercial aircraft. The model yields good results in most cases: in other cases, the model can be made to yield better agreement with the experimental results by making small changes in the property data. These changes are within the range of uncertainty of the property data. Author

THE OSU HEAT RELEASE RATE TEST USING THE OXYGEN CONSUMPTION PRINCIPLE **c25**

Yoshio Tsuchiya *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 225-232 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

The FAA Heat Release Rate (HRR) Test using the Ohio State University (OSU) apparatus can be improved by adopting the oxygen consumption principle. Using the present thermal method, the large heat input from the electrically-heated source of the radiative heat flux causes high baseline values in the output signals. The baseline value is easily and significantly changed by the thermal history of the apparatus and thermal disturbances. The heat absorbed by the apparatus and heat lost to the surroundings also cause errors. By using the oxygen consumption principle, these thermal errors can be eliminated. In Canada, a standard test method for measuring the HRR of low heat-releasing materials was developed. The method uses the OSU apparatus with the oxygen consumption principle. This method is useful for testing the heat release rate of airplane cabin materials. Only the addition of an oxygen analyzer is required for the present OSU apparatus and, thus, costs are minimized. PRACTICAL HAZARD ASSESSMENT: AN APPROACH TO THE FIRE SAFETY **c25**

Frederic B. Clarke and James R. Hoover (Du Pont de Nemours, E. I. and Co., Wilmington, DE.) *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 233-244 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Fire hazard assessment, although a powerful technique, is usually complex and elaborate. A simplified approach for practical use is presented, which relies on simple, closed-form relationships to allow potential regulators and product designers to estimate the effects which material product fire and smoke properties would have on the developing fire hazard in aircraft interiors. The four steps in the process, scenario analysis, setting objectives, formulating a fire protection strategy, and test method selection and criteria setting are described and an illustrative example aircraft wire and cable is briefly discussed. (Most criteria involve more than one fire/smoke property, so that considerable flexibility in meeting the criteria is allowed.) Author (revised)

FIRE RESISTANCE AND MECHANICAL PROPERTIES FOR PHENOLIC PREPREGS **c27**

Shahid P. Qureshi *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 245-253 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

Fire resistance performance, thermal analysis, and mechanical properties of glass fiber laminates prepared with four thermal cure phenol/formaldehyde resins are discussed. Prepregs for the laminates were produced by conventional solution process. This study was performed to optimize fire resistance (FR), and thermal and mechanical properties by changing formaldehyde/phenol (F/P) mole ratio. An optimum F/P ratio was identified for maximum fire resistance and thermal properties without any sacrifice in mechanical properties. The resins evaluated easily met Federal Aviation Administration (FAA) requirements for OSU heat release and NBS smoke tests. Also, all laminates exceeded the mechanical limits of MIL-R-9299C specifications. The resins are suitable for prepregs and honeycomb for aircraft interior applications. Author (revised)

DEVELOPMENTS NEEDED TO EXPAND THE ROLE OF FIRE MODELING IN MATERIAL FIRE HAZARD ASSESSMENT **c25**

Andrew J. Fowell *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 255-262 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

To assess the fire hazards associated with aircraft interior materials, prediction of how the materials perform under different fire scenarios is needed. This requires information on a variety of fire characteristics including thermal inertia, ease of ignition, rate of heat release, flame spread, products of combustion, and the response to suppressants. Exposure conditions such as location, orientation, ventilation, and proximity to other materials can influence some of those characteristics. Pass/fail test methods of the past cannot provide the information to assure fire safety under a variety of circumstances. Fire modeling in combination with new bench scale material flammability test methods can meet the need. National and international developments in model validation, documentation, and acceptance are presented. The transition to aircraft cabin fire hazard assessment using fire models requires a data base on material fire properties. The case is made for greater use of improved bench scale test methods which can provide data suitable for use in the fire models. Author (revised)

FLAMMABILITY PARAMETERS OF MATERIALS: IGNITION, COMBUSTION, AND FLAME SPREAD **c25**

A. Tewarson *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 263-281 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Flammability parameters associated with the ignition, combustion, and flame spread processes and their usefulness for the advanced fire resistant aircraft interior materials are discussed. The flammability parameters discussed are: (1) critical heat flux (CHF) and thermal response parameter (TRP), associated with ignition, (2) heat release parameter (HRP) and fire propagation index (FPI), associated with combustion and flame spread. The CHF, TRP, and HRP values can be derived from the data measured in the most commonly used apparatuses: (1) the Ohio State University (OSU) Heat Release Apparatus, which is the Federal Aviation Administration's (FAA) standard apparatus, (2) the Factory Mutual Research Corporation (FMRC) Flammability Apparatus, and (3) the National Institute of Standards and Technology (NIST) Flame Spread Apparatus (LIFT) and the Cone Calorimeter. The OSU and FMRC Apparatuses and the Cone Calorimeter generate very similar data for ignition and heat release rate for small horizontal and vertical samples under ambient conditions. The NIST LIFT and the FMRC Apparatuses generate very similar data for lateral, upward, and downward flame spread for slabs and cylinders under ambient conditions. The FMRC Apparatus is also used to perform Flame Radiation Scaling experiments to determine the range of flame radiative and convective flame heat fluxes transferred to the surface during combustion in small- to large-scale fires, pertinent to the aircraft interior material fire scenarios leading to flashover. The flammability parameters in terms of the fundamental scientific principles is described. Numerous examples of data are presented in tables and graphs. Author (revised)

FACTORS THAT AFFECT OSU THERMAL PERFORMANCE OF AIRCRAFT INTERIOR MATERIALS **c25**

Steven D. Beare *In* FAA, Proceedings of the International Conference

for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 283-296 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

Decorative tapestries for interior vertical surfaces of aircraft are a complex system of materials of varying levels of flammability. This system can include face fiber, dyes and adjuvants, lubricants, backing, latex, adhesive, and rigid core materials, each of which can affect thermal performance. A new easily dyeable fiber, NOMEX THERMACOLOR aramid fiber, was recently developed and exceeds FAA OSU thermal performance requirements and provides additional styling capability and reduced cycle time over producer colored NOMEX CGF. The systematic study of the carpet variables of pile height and weight, backing type, and latex type and weight on OSU thermal performance of cut pile tapestry carpets containing yarns of NOMEX THERMACOLOR fibers is described. Avail: CASI HC A02/MF A03

The Wright Laboratory Materials Directorate at WPAFB, Ohio recently completed a research and development program under contract with the McDonnell Douglas Aerospace Company, St. Louis, Missouri. Program objectives were to develop wire insulation performance requirements, evaluate candidate insulations, and prepare preliminary specification sheets on the most promising candidates. Aircraft wiring continues to be a high maintenance item and a major contributor to electrically-related aircraft mishaps. Mishap data on aircraft show that chafing of insulation is the most common mode of wire failure. Improved wiring constructions are expected to increase aircraft performance and decrease costs by reducing maintenance actions. In the laboratory program, new insulation constructions were identified that had overall improved performance in evaluation tests when compared to currently available MIL-W-81381 and MIL-W-22759 wiring. These insulations are principally aromatic polyimide and crosslinked ethylene tetrafluoroethylene (ETFE), respectively. Candidate insulations identified in preliminary specification sheets were principally fluoropolymers with a polyimide inner layer. Examples of insulation properties evaluated included flammability, high temperature mechanical and electrical performance, fluid immersion, and susceptibility to arc propagation under applied power chafing conditions. Potential next generation wire insulation materials are also reviewed. Author (revised)

FUTURE MATERIAL DEVELOPMENT TRENDS FOR COMMERCIAL AIRPLANE INTERIORS c27
Peter S. Guard and James M. Peterson *In* FAA, Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 313-319 (For primary document see N94-10766 01-03)
Avail: CASI HC A02/MF A03

Advances in airplane interiors in the past have, for the most part, been made by airplane manufacturers primarily through initiatives to improve safety, but also to update appearance and functionality. Recently, regulation has played a very large role in the design of airplane interiors. The Federal Aviation Administration (FAA) heat release rule was a major challenge to designers and materials suppliers, and required the development and incorporation of new materials on a very tight schedule. Industry was able to meet the rule, but the result was non-optimum solutions. It is suggested that all affected parties - regulatory and industry - work together in advance of regulation to continuously improve cabin furnishings. Strategic research and development programs involving all parties should be established, using an integrated material, design, and manufacturing philosophy. We have looked at how we can operate in a 'continuous improvement mode', and will share with how we are trying to incorporate this. Author (revised)

ADVANCED AIRCRAFT MATERIALS RESEARCH AND DEVELOPMENT PLAN c24
Richard Lyon and Thor Eklund *In its* Proceedings of the International Conference for the Promotion of Advanced Fire Resistant Aircraft Interior Materials Mar. 1993 p 345-364 (For primary document see N94-10766 01-03)
Avail: CASI HC A03/MF A03

The DOT/FAA Long-Range Fire Safety Research Plan is outlined and a preliminary strategy for developing advanced, fire-resistant, aircraft materials as an integral component of the program is discussed. Long-range research thrusts are also proposed in fire modeling, aircraft vulnerability analysis, improved systems, advanced suppression, and fuel safety. The research plan anticipates fire safety needs for next-generation aircraft and attempts to identify emerging materials and systems technologies where a focused, sustained research effort could lead to order-of-magnitude improvements in air transportation fire safety over the next two decades. The FAA's role in the proposed framework is to initiate and maintain a balanced program of basic university research, private-sector advanced development, and in house applied research to facilitate technology insertion. The FAA Fire Safety Research Plan describes programmatic opportunities for the public from the increased research funding sought by the FAA for this activity. Leveraging of research dollars will be accomplished through collaboration and cost-sharing with government agencies having similar fire safety requirements. Technology transfer will occur through FAA-sponsored meetings, scientific publications, industrial liaisons, and student internships at the FAA Technical Center. It is expected that fire safety needs of the construction, manufacturing, and chemical process industries will provide opportunities for the utilization of advanced fire safety technology beyond commercial aviation. The Fire Safety Branch at the Technical Center in Atlantic City, New Jersey, is the Federal Aviation Administration's (FAA) Research and Development (R&D) organization responsible for providing data to the regulatory organizations within the FAA for their use in developing, modifying, and/or interpreting rules and regulations pertaining to aircraft fire safety. The Fire Safety Branch has developed many of the fire safety standards adopted by civil aviation authorities throughout the world and is presently involved in R&D for future improvements. The Safety Regulation Group of the United Kingdom Civil Aviation Authority (CAA) initiates and funds research which is conducted by agencies external to the Authority. The research is 'Project Managed' by CAA staff working as a team involving technical experts, certification and regulatory specialists, and a project manager. There are programs of work in which the CAA together with other Authorities jointly manage complementary studies, an example is the research into Cabin Water Spray Systems which has involved the CAA, FAA, Transport Canada, DGAC of France, and the European Commission. In the future, it is expected that CAA research activities will increasingly involve other European Joint Aviation Authorities (JAA) as partners and become integrated into a JAA-wide program of research. (PB93-910405; NTSB/AAR-93/01/SUM) Avail: CASI HC A05/MF A01

The crash of N811BE into the Rhode Island Sound is explained. The safety issues discussed include the use of flight simulators rather than airplanes for training, the adequacy of FAA surveillance of Part 135 pilot training, and the adequacy of management oversight of pilot training for Part 135 commuter operators. FAA AIR TRAFFIC ACTIVITY Statistical Report, 1 Oct. 1991 - 30 Sep. 1992
Nancy Trembley 1992 252 p
(AD-A266043) Avail: CASI HC A12/MF A03

This FAA publication furnishes terminal and en route air traffic activity information of the National Airspace System. The data were reported by the FAA-operated Airport Traffic Control Towers (ATCT's), Air Route Traffic Control Centers (ARTCC's), Flight Service Stations, Approach Control Facilities, and FAA-contracted ATCT's. These reports are used as a guide in determining the need for larger or additional facilities, upgraded equipment at particular facilities, and possible increases in personnel at existing facilities. ANALYTICAL METHOD FOR WATER VAPOR COLLECTION AND ANALYSIS IN AIRCRAFT CABIN FIRES
Louise C. Speitel Aug. 1993 22 p
(DOT/FAA/CT-TN93/33) Avail: CASI HC A03/MF A01

The purpose of this work is to develop a method of quantifying water vapor in the presence of a complex mixture of airborne combustion products, to verify that this method is relatively free of interferences, and to demonstrate the applicability of this method to measure water vapor as a function-of-time in an aircraft cabin fire with and without water spray. This data was used to access whether there is an additional thermal inhalation hazard from the water vapor generated by water mist suppression of aircraft cabin fires. Author

NATIONAL AIRSPACE SYSTEM OPERATIONAL CONCEPT Final Report
William Trent and Thomas Pickerell Jun. 1993 567 p
(Contract DTFA01-91-Y-01004)
(DOT/FAA/SE-93/1; NAS-SR-130) Avail: CASI HC A24/MF A04

The Federal Aviation Administration (FAA) has established specific goals for modernization of the National Airspace System (NAS) over the next decade. These goals include the replacement and modernization of aging air traffic control and navigation equipment and the development of a more comprehensive and coordinated system design to reflect specific needs of the user and specialist communities, to enhance safety, to improve efficiency and capacity, and to reduce operating costs. The programs to achieve these objectives are documented in the Capital Investment Plan (CIP). In conjunction with the CIP, the FAA has prepared system engineering management documents to assist in the orderly development and integration of CIP programs. The NAS Systems Requirements Specification (NASSRS) is a compilation of requirements which describe the operational capabilities for the NAS as envisioned to exist by the year 2000. The organization of this NAS Operational Concept corresponds to the major paragraphs of the NASSRS and provides an in-depth discussion of the higher level descriptions found in the NASSRS. This operational concept provides an overview of the NAS along with operational sequence diagrams and operational scenario diagrams to amplify the eight major sections of the NASSRS.

THE MEMPHIS PRECISION RUNWAY MONITOR PROGRAM INSTRUMENT LANDING SYSTEM FINAL APPROACH STUDY Project Report
Martha R. Owen 24 May 1993 120 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts F19628-90-C-0002; DTFA01-93-Z-02012)
(AD-A266035; ATC-194; DOT/FAA/NR-92/11) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report documents the study of the lateral positions of aircraft on Instrument Landing System (ILS) approaches during the Memphis, Tennessee, Precision Runway Monitor (PRM) demonstration. The PRM is an advanced radar monitoring system that improved the arrival capacity of closely spaced parallel runways in poor weather conditions. The results of this study are used to assist in determining the minimum runway spacing that will be authorized for PRM. The objective of this study was to quantify the lateral character of ILS arrivals and the consequent impact on independent simultaneous ILS arrival on closely spaced parallel runways. The sensitivity of the arriving aircrafts' lateral positions to different variables such as visibility, wind runway, aircraft type, autopilot performance, and localizer beam width was determined. Also, the Memphis arrival data were compared to FAA Technical Center Chicago O'Hare approach data. The analysis was primarily based on surveillance reports of 4,000 ILS arrivals into Memphis International Airport, collected with the PRM AMPS sensor (ATCRBS Monopulse Processing System). A major result of the study was that lateral aircraft positions will not hamper independent arrivals to parallel runways spaced 3,400 feet apart, but will impede operations at 3,000 feet or smaller unless approach modifications are introduced. Lateral deviations were found to be most sensitive to reduced visibility and certain autopilots. Lateral deviations were also found to be somewhat more at Memphis relative to Chicago O'Hare. Recommendations for further data analysis and collection are discussed.

PERFORMANCE OF TRAFFIC-ALERT COLLISION AVOIDANCE (TCAS) ANTENNAS IN THE PRESENCE OF SCATTERERS
K. S. Sampath, R. G. Rojas, and W. D. Burnside Jul. 1993 142 p
(Grant NAG1-1058)
(NASA-CR-193569; NAS 1.26:193569; TR-722792-5) Avail: CASI HC A07/MF A02

The performance of two TCAS systems is studied in the presence of electromagnetic scatterers. TCAS is an aircraft mounted angle of arrival (AOA) system, which estimates the bearing of a signal transmitted from a mode-S transponder on another nearby aircraft (intruder). Two systems are studied: (1) Comparison of Relative Amplitude system (CRA), and (2) Spiral Phase Antenna (SPA). The CRA antenna receives the reply via four switched beams. The bearing is estimated by comparing the amplitudes of the received signal. The SPA is based on the phase interferometer, which utilizes the received phase via sum and difference beams. The AOA is computed by comparing the reply with similar values on a calibration table, which is generated by modeling the TCAS antenna on the bare fuselage of a Boeing 727-200. The antenna patterns for the TCAS are found via high frequency methods based on the Uniform Geometric theory of Diffraction (UTD). By minimizing the standard deviation of the bearing error in a specified angular sector, optimal locations for top and bottom mounted TCAS antennas are found on the Boeing 727-200, 737-300 and 747-200 airframes. It will be shown that the overall bearing errors of the amplitude system are consistently smaller than the spiral phase TCAS. The effect of two types of nearby scatterers--antennas, and engine inlets--is studied. The AT741 L-band blade, DMC60-1 VHF Communication antenna were chosen as being representative antenna interference examples. Models are derived for the blades via a moment method analysis followed by a least squares procedure to synthesize the scattering patterns. Studies were conducted to estimate the minimum separation between the two antennas for acceptable operation. It will be shown that the spiral phase TCAS is adversely affected by the presence of a blade antenna. The amplitude system does not suffer from this limitation, especially for the forward look angles which are of most interest here. A model to represent the inlet scattering is based on the multiple scattering method and UTD. The engine on top of the B727-200 fuselage is modeled by a terminated circular waveguide. Then, the effect of moving the antenna forward on the fuselage is studied. It is again shown that the performance of the amplitude system is superior.

IMPACT OF SHUTTING DOWN EN ROUTE PRIMARY RADARS WITHIN CONUS INTERIOR Final Report, Jun. 1992 - Feb. 1993
Janis Vilcans Jun. 1993 43 p
(DOT-VNTSC-FAA-93-1; DOT/FAA/NR-93-1) Avail: CASI HC A03/MF A01

The impact on the Air Traffic Control (ATC) operations resulting from the shutdown of all en route primary radars (except for ARSR-4s) within the CONUS interior will result in loss of real-time weather data and aircraft skin tracking over 33 percent primary surveillance loss of coverage in the CONUS and an increase in the accident rate of one accident in 11 years as predicted on recent statistics. The report concludes that real-time weather data while of limited quality must be retained until it can be replaced by data from the NEXRAD weather radar or other weather data source. Ability to track non-transponder equipped aircraft is significant but less critical and can be minimized by other system improvements. These include: better beacon radar (Mode S) in combination with Traffic Alert and Collision Avoidance System (TCAS) and Automatic Dependent Surveillance (ADS); increased transponder equipage; reduced altitude for non-transponder equipped aircraft to 10,000 feet; increased DF network to 370 sites; and better siting of beacon-only antennas. Based on current availability projections (derived from Capital Investment PLan (CIP) schedules) the most feasible en route primary radar shutdown date is the year 2008. If weather data from external sources can be made available on controllers displays before that time (for example by 1998 when ISSS is installed) that data can be advanced. Author (revised)

EVALUATION OF THE CAPACITY AND DELAY BENEFITS OF TERMINAL AIR TRAFFIC CONTROL AUTOMATION
Steven B. Boswell 14 Apr. 1993 76 p
(Contracts F19628-90-C-0002; DTFA01-88-Z-0200)
(AD-A265323; ATC-192) Avail: CASI HC A05/MF A01

The benefits that the Center/TRACON Automation System (CTAS) component of the FAA Terminal Air Traffic Control Automation program (TATCA) offers to aviation users are reviewed. In particular, the prospects that exist for increasing arrival capacity during Instrument Meteorological Conditions (IMC) by introducing CTAS functionality into current operations are reported. The impact of anticipated capacity gains on air traffic delays is analyzed. Savings in delay are translated into dollar savings using FAA statistics on the fleet-weighted direct cost of delay to domestic air carriers. Also, the value of passenger time is considered. Economic impacts are estimated and reported on an annualized, nationwide basis. Adopting FAA projections of future traffic growth, estimates of delay and attendant cost savings to air carriers and their passengers are provided for fiscal years 1995-2015. Taking the nominal estimate of a 12% gain in IMC arrival capacity, a nationwide implementation of CTAS would be estimated to save an average of 412,000 hours of air carrier delay annually over this 21-year period, and 273 million gallons of fuel per year. With current fuel and labor costs, this amounts to average direct operating savings to air carriers of $1.5 billion per year, and value to passengers of over $3 billion per year, in constant 1988 dollars. There may be factors outside the scope of this study that restrict the implementation of CTAS to certain sites, or that limit the weather conditions in which CTAS is effective. Methods are discussed for modifying benefits estimates in response to such considerations. DTIC

EVALUATION OF THE C/EC/KC-135 GROUND COLLISION AVOIDANCE SYSTEM (GCAS), STUDY 2 Final Report, 1 Feb. - 30 Apr. 1992
Justin D. Rueb, Jordan R. Kriss, and John A. Hassoun Mar. 1993 150 p
(AD-A265193; ASC-TR-93-5004) Avail: CASI HC A07/MF A02

This report represents the second of a two-study evaluation program. The first study evaluated the original Cubic GCAS algorithm in four distinct phases. Throughout the four phases, concerns and recommendations were forwarded to the System Program Office and to the Cubic Corporation. This resulted in modification of the algorithm prior to the next phase of the evaluation. Phase 1 efforts focused on the verification and validation of the algorithm. This phase simply established how well the algorithm predicted altitude loss based on current inputs. Phase 2 was the robot pilot model phase. During this phase, a computer pilot model tested the GCAS under different aircraft configurations and environmental conditions. The man-in-the-loop phase, Phase 3, used a subset of the configuration in Phase 2 in addition to a series of Instrument Landing System (ILS) runs to determine algorithm ability to accurately predict under realistic conditions (human reaction times). In the final phase, current operational pilots flew mission scenarios based on selected CFIT mishaps. This phase permitted an evaluation of the Cubic GCAS algorithm under real-world conditions. Study 2 used the same four-phase approach as that used during Study 1. However, the evaluation was performed on the newly revised Cubic algorithm. The revised algorithm incorporated more extensive changes than those conducted after each of the Study 1 phases. Additionally, Study 2 evaluated Phase 1-Phase 4 without any delay. Unlike Study 1, the algorithm was not returned to Cubic for modification prior to the next phases. DTIC

HELICOPTER APPROACH CAPABILITY USING THE DIFFERENTIAL GLOBAL POSITIONING SYSTEM
David N. Kaufmann Aug. 1993 58 p
(Contract NCC2-775)
(NASA-CR-177618; A-93110; NAS 1.26:177618) Avail: CASI HC A04/MF A01

The results of flight tests to determine the feasibility of using the Global Positioning System (GPS) in the differential mode (DGPS) to provide high accuracy, precision navigation and guidance for helicopter approaches to landing are presented. The airborne DGPS receiver and associated equipment is installed in a NASA UH-60 Black Hawk helicopter. The ground-based DGPS reference receiver is located at a surveyed test site and is equipped with a real-time VHF data link to transmit correction information to the airborne DGPS receiver. The corrected airborne DGPS information, together with the preset approach geometry, is used to calculate guidance commands which are sent to the aircraft's approach guidance instruments. The use of DGPS derived guidance for helicopter approaches to landing is evaluated by comparing the DGPS data with the laser tracker truth data. Both standard (3 degrees) and steep (6 degrees and 9 degrees) glidescope straight-in approaches were flown. DGPS positioning accuracy based on a time history analysis of the entire approach was 0.2 m (mean) +/- 1.8 m (2 sigma) laterally and -2.0 m (mean) +/- 3.5 m (2 sigma) vertically for 3 degree glidescope approaches, -0.1 m (mean) +/- 1.5 m (2 sigma) laterally and -1.1 m (mean) +/- 3.5 m (2 sigma) vertically for 6 degree glidescope approaches, and 0.2 m (mean) +/- 1.3 m (2 sigma) laterally and -1.0 m (mean) +/- 2.8 (2 sigma) vertically for 9 degree glidescope approaches. DGPS positioning accuracy at the 200 ft decision height on a standard 3 degree glidescope approach was 0.3 m (mean) +/- 1.5 m (2 sigma) laterally and -2.3 m (mean) +/- 1.6 m (2 sigma) vertically. These errors indicate that the helicopter position based on DGPS guidance satisfies the International Civil Aviation Organization Category 1 lateral and vertical accuracy requirements. Author

NONLINEAR STABILITY AND CONTROL STUDY OF HIGHLY MANEUVERABLE HIGH PERFORMANCE AIRCRAFT Final Report

R. R. Mohler 20 Jul. 1993 118 p
(Grant NAG1-1081)
(NASA-CR-193480; NAS 1.26:193480; OSU-ECE-NASA-93-03) Avail: CASI HC A06/MF A02

This project is intended to research and develop new nonlinear methodologies for the control and stability analysis of high-performance, high angle-of-attack aircraft such as HARV (F18). Past research (reported in our Phase 1, 2, and 3 progress reports) is summarized and more details of final Phase 3 research is provided. While research emphasis is on nonlinear control, other tasks such as associated model development, system identification, stability analysis, and simulation are performed in some detail as well. An overview of various models that were investigated for different purposes such as an approximate model reference for control adaptation, as well as another model for accurate rigid-body longitudinal motion is provided. Only a very cursory analysis was made relative to type 8 (flexible body dynamics). Standard nonlinear longitudinal airframe dynamics (type 7) with the available modified F18 stability derivatives, thrust vectoring, actuator dynamics, and control constraints are utilized for simulated flight evaluation of derived controller performance in all cases studied. Author (revised)

AERODYNAMIC MODEL IDENTIFICATION OF QUIET STOL EXPERIMENTAL AIRCRAFT ASKA FROM DYNAMIC FLIGHT TEST DATA [TEISOUON STOL JIKKENKI ASUKA NO DOUTEKI HIKOU SHIKEN NIYORU KUURIKI MODERU DOUTEI]

Masaaki Yanagihara and Toshio Bandou Jan. 1992 34 p In JAPANESE
(DE93-767967; NAL-TR-1138; JTN-93-80424) Avail: CASI HC A03/MF A01

A method to identify an aircraft aerodynamic model using dynamic flight tests was investigated by National Aerospace Laboratory (NAL). This method is subsequently being applied to flight test data of the Quiet Short Take-Off and Landing (QSTOL) experimental aircraft 'ASKA' to obtain its nonlinear non-dimensional aerodynamic model. Estimated static parameters were evaluated by comparing results from steady/quasi-steady state tests, whereas estimated dynamic parameters were compared with theoretical ones. In addition, an overall evaluation was performed by calculating simulated time histories using the identified model and comparing the results with recorded test data. Good correlations were obtained, except for configurations in which limited flight tests had been conducted, thereby demonstrating the effectiveness of this method. Author (NASDA)

DETERMINING XV-15 AEROELASTIC MODES FROM FLIGHT DATA WITH FREQUENCY-DOMAIN METHODS

C. W. Acree, Jr. and Mark B. Tischler May 1993 68 p Prepared in cooperation with Army Aviation Systems Command, Moffett Field, CA
(RTOP 505-61-51)
(NASA-TP-3330; A-91002; NAS 1.60:3330; USAATCOM-TR-93-A-004)
Avail: CASI HC A04/MF A01

The XV-15 tilt-rotor wing has six major aeroelastic modes that are close in frequency. To precisely excite individual modes during flight test, dual flaperon exciters with automatic frequency-sweep controls were installed. The resulting structural data were analyzed in the frequency domain (Fourier transformed). All spectral data were computed using chirp z-transforms. Modal frequencies and damping were determined by fitting curves to frequency-response magnitude and phase data. The results given in this report are for the XV-15 with its original metal rotor blades. Also, frequency and damping values are compared with theoretical predictions made using two different programs, CAMRAD and ASAP. The frequency-domain data-analysis method proved to be very reliable and adequate for tracking aeroelastic modes during flight-envelope expansion. This approach required less flight-test time and yielded mode estimations that were more repeatable, compared with the exponential-decay method previously used. Author

N94-10945 Aeronautical Systems Div., Wright-Patterson AFB, OH.

AN ENVIRONMENTAL STUDY OF THE NATIONAL AEROSPACE PLANE Final Report, 1 Dec. 1991 - 30 Dec. 1992

Charles Brown, Ted Wierzbanowski, Helmut Reda, and Gregory T. Duecker Dec. 1992 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A266071; ASC-TR-93-5007) Avail: CASI HC A03

The overall objective of the United States (US) National Aero-Space Plane (NASP) Program is to develop the hypersonic technologies required for future military and civilian aerospace plane systems to reduce payload cost to orbit and provide for flexible-responsive space operations. If successful, the NASP Program will be the stimulus for developing a whole new class of airbreathing hypersonic aircraft powered by clean-burning scramjet engines using liquid hydrogen as the primary fuel. As part of this development, the potential environmental impacts from these vehicles must be considered and analyzed. This process has been initiated using the NASP Program's proposed X-30 flight research vehicle and flight test program as a basis for analysis. Environmental issues addressed include the following: noise and sonic booms, stratospheric ozone depletion, public health and safety, hazardous materials/waste, air quality, biological and cultural resources, geology and soils, and water use. Although this study is not yet complete, preliminary analysis has determined that the X-30 vehicle and flight test program would have minimal environmental impact. DTIC

ADVANCED ROTORCRAFT FLIGHT SIMULATION: MODEL DEVELOPMENT, VALIDATION AND PARALLEL IMPLEMENTATION Ph.D. Thesis

Sriprakash Partha Sarathy 1992 243 p
Avail: Univ. Microfilms Order No. DA9312589

The development of parallel algorithms for the real-time rotorcraft flight simulation is addressed. The objective is to employ more refined models that better predict helicopter behavior. A new Rotating Blade Element (RBE) model is developed, implemented, and validated. The new model includes coupled blade flap, lag, and pitch motions. The development of a parallel version of this model, together with appropriate parallel algorithms, is discussed for all phases of the flight simulation model. The 14 processor Encore Multimax (shared memory MIMD) parallel computer is used to implement the parallel flight simulation code. Results for the sequential and parallel implementations are provided. The RBE formulation is compared with results from CAMRAD for the OH-6 helicopter. The fully coupled nonlinear forward flight trim results compare well with those of CAMRAD. The coupled blade response is validated against Runge-Kutta integration. The timing results from the parallel code demonstrated speed up factors between 10 and 12 for the trim and response tasks. Dissert. Abstr.

SUPERSONIC AIRPLANE STUDY AND DESIGN

Samson Cheung Jun. 1993 17 p Original contains color illustrations
(Contract NCC2-617)
(NASA-CR-193219; NAS 1.26:193219; MCAT-93-10) Avail: CASI HC A03/MF A01; 3 functional color pages

A supersonic airplane creates shocks which coalesce and form a classical N-wave on the ground, forming a double bang noise termed sonic boom. A recent supersonic commercial transport (the Concorde) has a loud sonic boom (over 100 PLdB) and low aerodynamic performance (cruise lift-drag ratio 7). To enhance the U.S. market share in supersonic transport, an airframer's market risk for a low-boom airplane has to be reduced. Computational fluid dynamics (CFD) is used to design airplanes to meet the dual constraints of low sonic boom and high aerodynamic performance. During the past year, a research effort was focused on three main topics. The first was to use the existing design tools, developed in past years, to design one of the low-boom wind-tunnel configurations (Ames Model 3) for testing at Ames Research Center in April 1993. The second was to use a Navier-Stokes code (Overflow) to support the Oblique-All-Wing (OAW) study at Ames. The third was to study an optimization technique applied on a Haack-Adams body to reduce aerodynamic drag. Author (revised)

GROUND VIBRATION AND FLIGHT FLUTTER TESTS OF THE SINGLE-SEAT F-16XL AIRCRAFT WITH A MODIFIED WING

David F. Voracek Jun. 1993 60 p
(RTOP 533-02-35)
(NASA-TM-104269; H-1906; NAS 1.15:104269) Avail: CASI HC A04/MF A01

The NASA single-seat F-16XL aircraft was modified by the addition of a glove to the left wing. Vibration tests were conducted on the ground to assess the changes to the aircraft caused by the glove. Flight Luther testing was conducted on the aircraft with the glove installed to ensure that the flight envelope was free of aeroelastic or aeroservoelastic instabilities. The ground vibration tests showed that above 20 Hz, several modes that involved the control surfaces were significantly changed. Flight test data showed that modal damping levels and trends were satisfactory where obtainable. The data presented in this report include estimated modal parameters from the ground vibration and flight flutter test. Author

FURTHER STUDIES USING MATCHED FILTER THEORY AND STOCHASTIC SIMULATION FOR GUST LOADS PREDICTION

Robert C. Scott, Anthony S. Pototzky (Lockheed Engineering and Sciences Co., Hampton, VA.), and Boyd III Perry Jul. 1993 15 p Presented at the AIAA 34th Structures, Structural Dynamics, and Materials Conference, La Jolla, CA, 19-21 Apr. 1993 Previously announced in IAA as N93-33932
(RTOP 505-63-50-15)
(NASA-TM-109010; NAS 1.15:109010) Avail: CASI HC A03/MF A01

This paper describes two analysis methods -- one deterministic, the other stochastic -- for computing maximized and time-correlated gust loads for aircraft with nonlinear control systems. The first method is based on matched filter theory; the second is based on stochastic simulation. The paper summarizes the methods, discusses the selection of gust intensity for each method and presents numerical results. A strong similarity between the results from the two methods is seen to exist for both linear and nonlinear configurations. Author

GENERAL AVIATION AIRCRAFT-NORMAL ACCELERATION DATA ANALYSIS AND COLLECTION PROJECT Final Report

James E. Locke, Howard W. Smith, Edward A. Gabriel, and Thomas DeFlore Feb. 1993 341 p
(AD-A265055; KR-FRL-926-1; DOT/FAA/CT-91/20) Avail: CASI HC A15/MF A03

The analysis and condensation of repeated flight loads obtained from 77 airplanes that participated in the NASA VGH General Aviation Program are reported. In addition, the load spectra for 98 airplanes in the NASA VGH data base are presented as plotted and tabulated data. Curve fit equations are listed for the original data and for extrapolation, which was used in the statistical analysis. Airspeed, normal load factor, and altitude were recorded continuously during flight. The load factor data were separated into gust and maneuver normal accelerations. The reduced data are presented as cumulative number of occurrences per nautical mile versus acceleration fraction (incremental normal acceleration divided by incremental limit load factor). For statistical analysis, the airplanes were grouped into seven single and twin-engine operational usage groups. The mean (weighted by flight time); weighted mean plus one, two, and three standard deviation spectra; and the 90% probability/95% confidence spectra were determined for each operational usage group and for several of the groups combined. An estimate of the scatter associated with groups having small sample size was determined by computing a pooled variance and pooled standard deviation. The resulting load spectra are to be used for wing fatigue test or safe-life estimation. DTIC

LIFT ENHANCEMENT OF A WING/STRAKE USING PNEUMATIC BLOWING M.S. Thesis

Craig J. Zgraggen Mar. 1993 92 p
(AD-A265074) Avail: CASI HC A05/MF A01

A low-speed wind-tunnel study to quantitatively measure the lift and drag effects of pneumatically controlling strake and leading-edge vortices generated by a half-span, generic-fighter model was conducted. The study measured the increase in lift and drag on the model throughout a range of angles of attack. The study utilized various blowing tubes of different geometries and orientations. Results showed that blowing produced changes in lift with minimal effect on drag. Blowing appeared to reattach flow during the initial stages of stall. Blowing increased lift a maximum of 9 percent at an angle of attack of 20 degrees, and up to 7 percent at angles of attack greater than 20 degrees. Blowing rates were varied from C(sub mu) of 0.0094 to C(sub mu) of 0.022. Near axial blowing produced the largest increases in lift. It was found that lift increases were directly proportional to changes in blowing rate. DTIC

AIRCRAFT WINDSCREENS ENHANCE VISUAL SEARCH DISRUPTION PRODUCED BY LASER GLARE Interim Report

J. A. DAndrea, R. N. Shull, and J. C. Knepton, Jr. Dec. 1992 16 p
(AD-A265167; NAMRL-1380) Avail: CASI HC A03/MF A01

Naval aircrews may be exposed to laser radiation that is used for a variety of purposes. Consequently, there is high probability of both deliberate and accidental exposure of personnel to laser radiation. One deliberate use of laser radiation may be as a mission deterrent to disrupt aircrew visual performance. The purpose of this study was to determine how low-intensity laser glare interacts with an aircraft windscreen and if flat or wraparound aircraft windscreens differentially enhance glare and disrupt visual search performance. In addition, we evaluated the effectiveness of laser glare in high ambient light. Visual search time to locate target disks viewed through either a flat or curved windscreen under laser glare conditions was significantly longer compared to a no glare control. The glare pattern and disruption of visual search under low ambient light, simulating dawn or dusk, was more extensive when viewed through a wraparound F/A-18 windscreen than a flat A/4 windscreen. Detection of targets also depended on their location relative to the center of the laser glare pattern. Visual search performance returned to baseline levels under daytime ambient lighting conditions. The results of this experiment illustrate that aircraft windscreens can significantly increase laser-produced glare as measured by a visual search performed under low levels of ambient lighting. Eye protection is needed to prevent mission disruption, even at laser intensities that are not harmful to the eye. DTIC

(Contract NAS9-17900)
(NASA-CR-188253; NAS 1.26:188253; LESC-30749) Avail: CASI HC A04/MF A01

The objective of this study was to develop a topology for describing the behavior of mission, vehicle and system/substem entities in new flight vehicle designs based on the use of open standards. It also had to define and describe the modes and states which may be used in generic avionics behavioral descriptions, describe their interrelationships, and establish a method for applying generic avionics to actual flight vehicle designs.

STUDIES ON SCRAMJET NOZZLES. PART 1: PERFORMANCE OF TWO DIMENSIONAL NOZZLES [SUKURAMU JETTO NOZURU NO KENKTUU. SONO 1: NIJIGEN NOZURU NO SEINOU]
Hiroshi Miyajima, Tooru Mitani, Shigeru Satou, Shuuichi Ueda, Kouichirou Tani, Tetsuo Hiraiwa, Katsuhiro Itou, Kazuo Kusaka, Muneo Izumikawa, and Atsushige Tanaka et al Apr. 1992 54 p In JAPANESE
(NAL-TR-1149; JTN-93-80438; DE93-793617) Avail: CASI HC A04/MF A01

A series of experiments was conducted for studying scramjet nozzle performance under Mach 8 flight conditions using high temperature gas flow with Mach 2.5. MonoMethyl Hydrazine (MMH) and Nitrogen TetraOxide (NTO) were adopted to produce high temperature gas flow. The stagnation temperature was designed to be 3,170 K, and the stagnation pressure to be 1 MPa. A simple configuration by plane walls was selected for the scramjet nozzle. Thrust by the scramjet nozzles with expansion ratios of 3 (EN3) and 5 (EN5) was examined. The experiments were performed using a thrust measuring system installed in a high altitude test facility. Delivered specific impulse I(sub sp) by MMH/NTO combustion was found to be 17.3 sec (EN3) to 26.1 sec (EN5). These small increments of I(sub sp) in the scramjet nozzles, however, correspond to I(sub sp) gains of about 1,100 sec for H2 fueled scramjets. Performances of nozzles were predicted using computer codes, and energy release loss, kinetic loss, and two-dimensional loss were identified. The two-dimensional loss was predicted to be 16.5 percent in the EN3 nozzle and to decrease to 7.0 percent in the EN5 nozzle. The kinetic loss due to chemical freezing was found to be 4.4 percent (EN3) and 3.0 percent (EN5). The nozzle performance could be compared with the experimental results. A friction loss (12.4 percent) measured by thrusts suggested laminar flow in the scramjet nozzle used in the MMH/NTO experiments. Measured heat flux on nozzles also supported the laminar boundary layer.

NUMERICAL CALCULATION OF SCRAMJET INLET FLOW
Tomiko Ishiguro, Satoru Ogawa, and Yasuhiro Wada Jul. 1992 31 p
(NAL-TR-1174T; JTN-93-80447; DE93-793626) Avail: CASI HC A03/MF A01

A numerical procedure to analyze flowfields through and around the Langley-type scramjet engine inlet is proposed. To accurately treat boundary conditions (walls, edges, etc.), all boundaries are mapped onto certain parts of the faces of three rectangular parallelepipeds. A computational space is made by connecting them. The three dimensional full Navier-Stokes equations which include the Baldwin-Lomax algebraic turbulent model are solved by applying the TVD (Total Variation Diminishing) scheme to the uniform mesh points of the space. To exhibit capability of the numerical procedure, parametric studies on flow simulations were carried out by fixing freestream Reynolds number Re = rho(sub infinity) x c(sub infinity) x L/mu(sub infinity) = 5.3 x 10(exp 5) under various trios of a freestream Mach number M(sub infinity), a sweep angle of leading edge of side plate beta and an entrance/throat contraction ratio R (M(sub infinity) approximately equals 2 to 10, beta approximately equals 0 deg to 60 deg, R approximately equals 3 to 10). The influence of the parameters on inlet performances (a mass capture ratio, a total pressure recovery ratio, and possibility of starting) is discussed. The results are in good agreements with the experiments under M(sub infinity) = 4 in starting cases, where iterated reflective oblique shock waves made by wedges of side panels decelerate and compress air. Unstarting phenomenon was analyzed in cases either of low M(sub infinity) or high R. Author (NASDA)

DEVELOPMENT OF AN UNSTRUCTURED SOLUTION ADAPTIVE METHOD FOR THE QUASI-THREE-DIMENSIONAL EULER AND NAVIER-STOKES EQUATIONS

Yi-Tsann Jiang Jul. 1993 267 p
(Grant NAG3-1127; RTOP 505-62-10)
(NASA-CR-191161; E-7967; NAS 1.26:191161) Avail: CASI HC A12/MF A03

A general solution adaptive scheme-based on a remeshing technique is developed for solving the two-dimensional and quasi-three-dimensional Euler and Favre-averaged Navier-Stokes equations. The numerical scheme is formulated on an unstructured triangular mesh utilizing an edge-based pointer system which defines the edge connectivity of the mesh structure. Jameson's four-stage hybrid Runge-Kutta scheme is used to march the solution in time. The convergence rate is enhanced through the use of local time stepping and implicit residual averaging. As the solution evolves, the mesh is regenerated adaptively using flow field information. Mesh adaptation parameters are evaluated such that an estimated local numerical error is equally distributed over the whole domain. For inviscid flows, the present approach generates a complete unstructured triangular mesh using the advancing front method. For turbulent flows, the approach combines a local highly stretched structured triangular mesh in the boundary layer region with an unstructured mesh in the remaining regions to efficiently resolve the important flow features. One-equation and two-equation turbulence models are incorporated into the present unstructured approach. Results are presented for a wide range of flow problems including two-dimensional multi-element airfoils, two-dimensional cascades, and quasi-three-dimensional cascades. This approach is shown to gain flow resolution in the refined regions while achieving a great reduction in the computational effort and storage requirements since solution points are not wasted in regions where they are not required. A RECOMMENDED METHODOLOGY FOR QUANTIFYING NDE/NDI BASED ON AIRCRAFT ENGINE EXPERIENCE [LE PROJET DE METHODOLOGIE POUR L'EVALUATION DU CONTROLE NON-DESTRUCTIF FONDE SUR L'EXPERIENCE ACQUISE SUR LES MOTEURS D'AVIONS]

Apr. 1993 85 p Lectures held in Ankara, Turkey, 26-27 Apr. 1993, in Lisbon, Portugal, 29-30 Apr. 1993, in Patras, Greece, 4 May 1993, and in Ottawa, Canada, 3-4 Jun. 1993
(AGARD-LS-190; ISBN-92-835-0707-X) Copyright Avail: CASI HC A05/MF A01

Methods to quantify nondestructive inspection (NDI) reliability and capability have been evolving for over twenty-five years. Initial attempts were qualitative rather than quantitative. With the advent of damage tolerance methodologies, it has become imperative to express more accurately probability of detection for a given inspection method and inspection system. This Lecture Series is aimed at providing a methodology to quantify probability of detection. This methodology includes, but is not limited to, design of experiments, specimen generation and maintenance, statistical analyses, data reduction and presentation, evaluation of inspection results in retirement for cause decisions, and the procedure required to establish a reliable probability based inspection for detecting anomalies in engine parts. The material to be presented is applicable to civil as well as military aircraft and turbine engine manufacturing and maintenance organizations. The lectures will examine the detection capabilities of fluorescent penetrant inspection, eddy current, ultrasonic, and magnetic particle inspection. This Lecture Series incorporates lessons learned in the design of experiments to validate nondestructive evaluation (NDE)/NDI systems and in the interpretation of the results of these experiments. Samples of specimens used in NDE/NDI reliability programs will be available for inspection by attendees. The Lecture Series also includes examples to help with the understanding of design of experiments and the statistical modeling for probability of detection analyses. This Lecture Series, sponsored by the Structures and Materials Panel of AGARD, was implemented by the Consultant and Exchange Program. Author (revised)

PRELIMINARY SUPERSONIC FLIGHT TEST EVALUATION OF PERFORMANCE SEEKING CONTROL

John S. Orme and Glenn B. Gilyard Washington Jun. 1993 20 p Presented at the 29th AIAA/SAE/ASME/ASEE Joint Propulsion Conference, Monterey, CA, 28-30 Jun. 1993
(RTOP 533-02-34)
(NASA-TM-4494; H-1909; NAS 1.15:4494; AIAA Paper 93-1821) Avail: CASI HC A03/MF A01

Digital flight and engine control, powerful onboard computers, and sophisticated controls techniques may improve aircraft performance by maximizing fuel efficiency, maximizing thrust, and extending engine life. An adaptive performance seeking control system for optimizing the quasi-steady state performance of an F-15 aircraft was developed and flight tested. This system has three optimization modes: minimum fuel, maximum thrust, and minimum fan turbine inlet temperature. Tests of the minimum fuel and fan turbine inlet temperature modes were performed at a constant thrust. Supersonic single-engine flight tests of the three modes were conducted using varied after burning power settings. At supersonic conditions, the performance seeking control law optimizes the integrated airframe, inlet, and engine. At subsonic conditions, only the engine is optimized. Supersonic flight tests showed improvements in thrust of 9 percent, increases in fuel savings of 8 percent, and reductions of up to 85 deg R in turbine temperatures for all three modes. The supersonic performance seeking control structure is described and preliminary results of supersonic performance seeking control tests are given. These findings have implications for improving performance of civilian and military aircraft. Author (revised)

APPLICATION OF JET-SHEAR-LAYER MIXING AND EFFERVESCENT ATOMIZATION TO THE DEVELOPMENT OF A LOW-NO(x) COMBUSTOR Ph.D. Thesis - Purdue Univ.

Renato Olaf Colantonio Jun. 1993 72 p
(RTOP 535-05-10)
(NASA-TM-105888; E-7353; NAS 1.15:105888) Avail: CASI HC A04/MF A01

An investigation was conducted to develop appropriate technologies for a low-NO(x), liquid-fueled combustor. The combustor incorporates an effervescent atomizer used to inject fuel into a premixing duct. Only a fraction of the combustion air is used in the premixing process to avoid autoignition and flashback problems. This fuel-rich mixture is introduced into the remaining combustion air by a rapid jet-shear-layer-mixing process involving radial fuel-air jets impinging on axial air jets in the primary combustion zone. Computational analysis was used to provide a better understanding of the fluid dynamics that occur in jet-shear-layer mixing and to facilitate a parametric analysis appropriate to the design of an optimum low-NO(x) combustor. A number of combustor configurations were studied to assess the key combustor technologies and to validate the modeling code. The results from the experimental testing and computational analysis indicate a low-NO(x) potential for the jet-shear-layer combustor. Key parameters found to affect NO(x) emissions are the primary combustion zone fuel-air ratio, the number of axial and radial jets, the aspect ratio and radial location of the axial air jets, and the radial jet inlet hole diameter. Each of these key parameters exhibits a low-NO(x) point from which an optimized combustor was developed. Using the parametric analysis, NO(x) emissions were reduced by a factor of 3 as compared with the emissions from conventional, liquid-fueled combustors operating at cruise conditions. Further development promises even lower NO(x) with high combustion efficiency. Author (revised)

A03/MF A01; 5 functional color pages

A spray combustor, with flow velocities in the laminar range, exhibits a unique operating mode where large amplitude, self-induced oscillations of the flame shape occur. The phenomenon, not previously encountered, only occurs when fuel is supplied in the form of fine liquid droplets and does not occur when fuel is supplied in gaseous form. Several flow mechanisms are coupled in such a fashion as to trigger and maintain the oscillatory motion of the flame. These mechanisms include heat transfer and evaporation processes, dynamics of two-phase flows, and effects of gravity (buoyancy forces). An interface volume, lying above the fuel nozzle and below the flame was found to be the most susceptible to gravity effects and postulated to be responsible for inducing the oscillatory motion. Heptane fuel was used in the majority of the tests. Tests performed with iso-octane also showed similar results. Author (revised)

A COMPARISON BETWEEN NUMERICALLY MODELLED AND EXPERIMENTALLY MEASURED LOSS MECHANISMS IN WAVE ROTORS
Daniel E. Paxson Jun. 1993 13 p Presented at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-20 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE
(RTOP 505-62-50)
(NASA-TM-106279; AIAA Paper 93-2522; E-8018; NAS 1.15:106279)
Avail: CASI HC A03/MF A01

A numerical model has been developed which is capable of predicting the performance of a wave rotor (pressure exchanger) of specified geometry over a wide range of operating conditions. The model can account for the major loss mechanisms of leakage from the tube ends, fluid viscosity, heat transfer to the tube walls, finite tube opening time, shock waves, and non-uniform port flows. It is a one dimensional flow model which follows a single tube as it rotates past the various stationary ports. Since the model is relatively simple (i.e. one dimensional) it uses little computer time. This makes it suitable for design as well as analytical purposes. This paper will present a brief description of the model then discuss a comparison between the model predictions and several wave rotor experiments. Author (revised)

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

ICING OF TURBINE INTAKE LOUVERS Special Report
Michael R. Walsh, Donald E. Garfield, James S. Morse, Kurt V. Knuth, and Nathan D. Mulherin Apr. 1993 43 p
(AD-A265714; CRREL-SR-93-4) Avail: CASI HC A03/MF A01

Superstructure icing is a phenomenon that can have debilitating effects on the operation of any ship. When designing ships that will operate in environments where icing may occur, careful consideration must be given to minimizing the accumulation and effect of superstructure icing. Such consideration was given to the U.S. Navy DDG-51-class destroyer when new turbine intake louvers were proposed. To ensure that sufficient air would be available to the vessel's gas turbines and ventilation system during an icing event, the Navy asked the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL), through Advanced Marine Enterprises, Inc., (AME) of Arlington, Virginia, to conduct a series of comparative icing tests between standard intake louvers and a new louver design. IN-FLIGHT SIMULATION OF BACKSIDE OPERATING MODELS USING DIRECT LIFT CONTROLLER [DLC WO MOCHIITA BAKKUSAIDO MODERU NO IN FURAITO SHIMYURESHON]
Yuukichi Tsukano and Toshiharu Inagaki Apr. 1992 18 p In JAPANESE
(NAL-TR-1152; JTN-93-80433; DE93-767976) Avail: CASI HC A03/MF A01

Effectiveness of a Direct Lift Controller (DLC) for in-flight simulation is discussed. A DLC device has been shown to be indispensable for in-flight simulation of backside operating models, hence quick-moving flaps were installed on the Variable Stability and Response Airplane (VSRA) of the National Aerospace Laboratory (NAL) of Japan. After tailoring feedback and feed-forward gains, a model-following system was constructed to simulate backside operating mother aircraft. Flight verification test results are included and indicate that a DLC is helpful but not required for simulating frontside operating models, whereas it is mandatory to obtain acceptable model following errors necessary to simulate backside operating models. Flight test results for a simulated landing approach in the backside region are also presented. Author (NASDA)

The addition of a large movable horizontal tail surface to the control system of a rotorcraft in-flight simulator being developed from a Sikorsky UH-60A Black Hawk Helicopter is evaluated. The capabilities of the control surface as a trim control and as an active control are explored. The helicopter dynamics are modeled using the Generic Helicopter simulation program developed by Sikorsky Aircraft. The effect of the horizontal tail on the helicopter trim envelope is examined by plotting trim maps of the aircraft attitude and controls as a function of the flight speed and horizontal tail incidence. The control power of the tail surface relative to that of the other controls is examined by comparing control derivatives extracted from the simulation program over the flight speed envelope. The horizontal tail's contribution as an active control is evaluated using an explicit model following control synthesis involving a linear model of the helicopter in steady, level flight at a flight speed of eighty knots. The horizontal tail is found to provide additional control flexibility in the longitudinal axis. As a trim control, it provides effective control of the trim pitch attitude at mid to high forward speeds. As an active control, the horizontal tail provides useful pitching moment generating capabilities at mid to high forward speeds. Author (revised)

CRITERIA FOR DESIGN OF INTEGRATED FLIGHT/PROPULSION CONTROL SYSTEMS FOR STOVL FIGHTER AIRCRAFT
James A. Franklin Apr. 1993 34 p Sponsored by NASA. Washington
(RTOP 533-02-37)
(NASA-TP-3356; A-93038; NAS 1.60:3356) Avail: CASI HC A03/MF A01

As part of NASA's program to develop technology for short takeoff and vertical landing (STOVL) fighter aircraft, control system designs have been developed for a conceptual STOVL aircraft. This aircraft is representative of the class of mixed-flow remote-lift concepts that was identified as the preferred design approach by the U.S./U.K. STOVL Joint Assessment and Ranking Team. The control system designs have been evaluated throughout the powered-lift flight envelope on the Vertical Motion Simulator (VMS) at Ames Research Center. Items assessed in the control system evaluation were: maximum control power used in transition and vertical flight, control system dynamic response associated with thrust transfer for attitude control, thrust margin in the presence of ground effect and hot-gas ingestion, and dynamic thrust response for the engine core. Effects of wind, turbulence, and ship airwake disturbances are incorporated in the evaluation. Results provide the basis for a reassessment of existing flying-qualities design criteria applied to STOVL aircraft. Author

Avail: CASI HC A03/MF A01

A parameter optimization framework has earlier been developed to solve the problem of partitioning a centralized controller into a decentralized, hierarchical structure suitable for integrated flight/propulsion control implementation. This paper presents results from the application of the controller partitioning optimization procedure to IFPC design for a Short Take-Off and Vertical Landing (STOVL) aircraft in transition flight. The controller partitioning problem and the parameter optimization algorithm are briefly described. Insight is provided into choosing various 'user' selected parameters in the optimization cost function such that the resulting optimized subcontrollers will meet the characteristics of the centralized controller that are crucial to achieving the desired closed-loop performance and robustness, while maintaining the desired subcontroller structure constraints that are crucial for IFPC implementation. The optimization procedure is shown to improve upon the initial partitioned subcontrollers and lead to performance comparable to that achieved with the centralized controller. This application also provides insight into the issues that should be addressed at the centralized control design level in order to obtain implementable partitioned subcontrollers. Author (revised)

MOVING-BASE SIMULATION EVALUATION OF THRUST MARGINS FOR VERTICAL LANDING FOR THE NASA YAV-8B HARRIER AIRCRAFT
James A. Franklin and Michael W. Stortz Mar. 1993 26 p
(RTOP 505-59-36)
(NASA-TM-104008; A-93051; NAS 1.15:104008) Avail: CASI HC A03/MF A01

A simulation experiment was conducted on Ames Research Center's Vertical Motion Simulator to evaluate the thrust margin for vertical landing required for the YAV-8B Harrier. Two different levels of ground effect were employed, representing the aircraft with or without lift improvement devices installed. In addition, two different inlet temperature profiles were included to cover a wide range of hot gas ingestion. For each ground effect and hot gas ingestion variant, vertical landings were performed at successively heavier weights, with the pilot assessing the acceptability of the operation in each case. Results are presented as a function of hover weight ratio and a metric of the mean ground effect and ingestion that reflect the increase in thrust margin required to provide acceptable control of sink rate during the descent to touchdown with increasing suck down and hot gas ingestion. CHAOTIC TIME SERIES ANALYSIS **c70**
Jaroslav Stark *In* AGARD, Stability in Aerospace Systems Feb. 1993 11 p (For primary document see N94-11489 01-08)
Copyright Avail: CASI HC A03/MF A03

This paper begins with a brief description of the basic theoretical framework for analyzing chaotic time series and then goes on to discuss recent work in this area in the Long Range Research Laboratory. As a particular example, we shall show how the ability to make short term predictions of chaotic time series can be used to extract small signals from a complex deterministic background. Experiments with simulated data have shown that it is possible to recover signals to a reasonable accuracy in situations where the ratio of amplitudes of signal to chaotic background is as low as 10(exp -5):1. ON NON-LINEAR LONGITUDINAL STABILITY OF AN AIRCRAFT IN A DIVE IN THE PRESENCE OF ATMOSPHERIC DISTURBANCES
L. M. B. C. Campos (Instituto Superior Tecnico, Lisbon, Portugal.) and A. A. Fonseca (Instituto Superior Tecnico, Lisbon, Portugal.) *In* AGARD, Stability in Aerospace Systems Feb. 1993 19 p (For primary document see N94-11489 01-08)
Copyright Avail: CASI HC A03/MF A03

We consider the nonlinear longitudinal stability problem of aircraft starting a dive from an initial velocity far removed from the steady dive speeds: the aim is to find a pitch control law, which will keep the aircraft in a constant glide slope, compensating for the phugoid mode. The problem is extended to account for the presence of arbitrary atmospheric winds, e.g., windshears. The theoretical stability curves are compared with flight test data, obtained using the BAFR (Basic aircraft for flight research) in Portugal. The model includes a number of effects, and has also some restrictions, which do not affect its suitability for the present application: (1) it includes compensation of the phugoid, but not short-period, mode i.e., neglects rotational inertia; (2) it accounts for boundary-layer and induced drag, but not wave drag, i.e., applies at low Mach numbers, typical of approach to land; (3) it neglects lateral motion, but allows for non-linear effects on longitudinal motion; and (4) it leads to a free-flying control law, in stall free conditions, and in the absence of autopilot or active control. These additional effects would be relevant to other applications, and would require extension or modification of the present model. Derived from text

DYNAMICS AND CONTROL OF COHERENT STRUCTURES IN THE TURBULENT WALL LAYER: AN OVERVIEW
Gal Berkooz, Philip Holmes, and John Lumley *In* AGARD, Stability in Aerospace Systems Feb. 1993 5 p Sponsored by NASA. Langley Research Center; AFOSR; ONR; and NSF (For primary document see N94-11489 01-08)
Copyright Avail: CASI HC A01/MF A03

We expand the velocity field in the vicinity of the wall in empirical eigenfunctions obtained from experiment. Truncating our system and using Galerkin projection, we obtain a closed set of non-linear ordinary differential equations with ten degrees of freedom. We find a rich dynamical behavior, including in particular a heteroclinic attracting orbit giving rise to intermittency. The intermittent jump from one attracting point to the other resembles in many respects the bursts observed in experiments. Specifically, the time between jumps and the duration of the jumps, is approximately that observed in a burst; the jump begins with the formation of a narrowed and intensified updraft, like the ejection phase of a burst, and is followed by a gentle, diffuse downdraft like the sweep phase of a burst. The magnitude of the Reynolds stress spike produced during a burst is limited by our truncation. The behavior is quite robust, much of it being due to the symmetries present (Aubry's group has examined dimensions up to 128 with persistence of the global behavior). We have examined eigenvalues and coefficients obtained from experiment, and from exact simulation, which differ in magnitude. Similar behavior is obtained in both cases; in the latter case, the heteroclinic orbits connect limit cycles instead of fixed points, corresponding to cross-stream waving of the streamwise rolls. The bifurcation diagram remains structurally similar, but somewhat distorted. The role of the pressure term is made clear - it triggers the intermittent jumps, which otherwise would occur at longer and longer intervals, as the system trajectory is attracted closer and closer to the heteroclinic cycle. The pressure term results in the jumps occurring at essentially random times, and the magnitude of the signal determines the average timing. Stretching of the wall region shows that the model is consistent with observations of polymer drag reduction. Change of the third order coefficients, corresponding to acceleration or deceleration of the mean flow, changes the heteroclinic cycles from attracting to repelling, increasing or decreasing the stability, in agreement with observations. The existence of fixed points is an artifact introduced by the projection; however, a decoupled model still displays the rich dynamics. Numerous assumptions made in Aubry et al. (1988) can now be proved exactly. Feeding back eigenfuncitons with the proper phase can delay the bursting, (the heteroclinic jump to the other fixed point), decreasing the drag. It is also possible to speed up the bursting, increasing mixing to control separation. Our approach is optimal for short time tracking in control. Author

CHAOS, ENTROPY, AND REVERSIBILITY: A SIMPLE EXAMPLE **c70**
C. Marchal *In* AGARD, Stability in Aerospace Systems Feb. 1993 3 p (For primary document see N94-11489 01-08)
Copyright Avail: CASI HC A01/MF A03

The contradiction between mathematical reversibility and physical irreversibility has traditionally led to the suspicion of 'hidden correlations' that will allow, in some cases, the decrease of the entropy of isolated systems. This idea seems wrong, as shown by a very simplified model. The true reason of the physical irreversibility is certainly the very large number of parameters of irreversible systems. In a rigorous manner, aircraft motion can be described by a set of nonlinear differential equations, depending of parameters, associating the state vector (angle of attack, sideslip angle, speed ...) with the control vector (motivators) through flight dynamics equations, aerodynamic aircraft model, and flight control system. The communication presents some works which aim at a better understanding and at the precise prediction of aircraft behavior in particular flight phases for which classical linearized analysis of differential equations is insufficient or not valid. DECOUPLING OF AIRCRAFT RESPONSES

David J. Moorhouse *In* AGARD, Stability in Aerospace Systems Feb. 1993 9 p (For primary document see N94-11489 01-08)

Copyright Avail: CASI HC A02/MF A03

The theory of aircraft stability is at least as old as powered flight. The original impetus was to design the configuration to have acceptable characteristics. Flight control technology was next applied to tailor, i.e. improve, the classical response characteristics: a yaw damper being a simple example. More recent flight control technology has provided the means to change the character of the aircraft response so that it no longer exhibits the classical behavior of a short period, a phugoid, a Dutch roll, a roll mode, and a spiral. With additional control effectors and the use of feedback there is an infinite number of ways to change the basic stability and response characteristics. Pilot preferences are also well established, however, so that care is needed in implementing any theoretical improvements. The technology exists to provide the pilot with the capability to individually control all six degrees of freedom. Obviously, a requirement for a pilot to integrate six different control effectors would be likely to increase his workload. In that sense, decoupling all six axes would be detrimental. Conversely, any unwanted coupling that can be eliminated should reduce the pilot task. The Wright Laboratory has had a series of flight demonstration programs that have evaluated new technologies in the most realistic tasks. First, an F-16 was provided with the additional control effectors to allow independent control of all six degrees of freedom. A variety of control modes was mechanized, so that the pilot could evaluate both coupled and decoupled modes. Following a subjective in-flight assessment, a ground-based piloted simulation experiment was performed to evaluate all modes for both offensive and defensive combat use. Second, an F-15 was modified to facilitate precise landing in adverse conditions. A special short landing mode was implemented to feature decoupling of airspeed and glideslope responses plus the integrated coupling of direct lift and sideforce control. This paper presents results from both these programs to illustrate the benefits of either decoupling or new coupling of aircraft responses. Derived from text

BOUNDARY LAYER TRANSITION: PREDICTION AND WIND TUNNEL SIMULATION **c34**

D. Arnal *In* AGARD, Stability in Aerospace Systems Feb. 1993 12 p (For primary document see N94-11489 01-08)

Copyright Avail: CASI HC A03/MF A03

This paper gives a survey of theoretical and experimental results related to the problem of boundary layer transition; emphasis is given on applications of practical prediction methods. In the first part of the paper, it is shown that the linear stability theory can provide a good estimate of the transition location if the free stream disturbance level is low enough; the difficulties to properly simulate free flight conditions in ground facilities is underlined. The second part of the paper is devoted to the problem of boundary layer tripping in the presence of large external disturbances; in this case, the linear theory no longer applies and empirical criteria need to be developed. Results from systematic wind tunnel tests of the dynamic roll behavior of a 65 degree swept delta wing at moderate (15 to 35 degree) angles of attack are reviewed. These tests, conducted in both the IAR 2 x 3 m low-speed wind tunnel and the 7 x 10 ft SARL facility at WPAFB, included static, forced oscillation and free-to-roll experiments with flow visualization. Multiple stable trim points (attractors) for body-axis rolling motions and other hard-to-explain dynamic behavior were observed. These data are examined in light of the nonlinear indicial response theory advanced by Tobak and his colleagues. The current analysis shows that force and moment, free-to-roll motion, and flow visualization data all confirm the existence of 'critical states' with respect to the static roll angle. When these singularities are encountered in a dynamic situation, large and persistent transients are induced. Conventional means of representing the nonlinear force and moments in the equations of motion are shown to be inadequate in these cases. Alternative approaches based on simplification of the nonlinear indicial model are briefly discussed. Derived from text

STABILITY MODEL OF THE ATMOSPHERE **c46**

Andreas Knueppel, Daniel Martens, and Andreas Siemer (Technische Univ., Hamburg, Germany.) *In* AGARD, Stability in Aerospace Systems Feb. 1993 17 p (For primary document see N94-11489 01-08)

Copyright Avail: CASI HC A03/MF A03

The atmosphere of the earth is a very complex system covering a wide range of interacting scales. The concept of stability is applied to subsystems thereof where the quantities involved in a stability analysis depend on the particular question to be answered. But all stability considerations share a common basic structure. After giving a short account to the nature of stability investigations, some examples of stability related atmospheric phenomena are presented which are relevant for flight operation. Finally, the impact of atmospheric instability on aircraft performance with special regard to flight safety is illustrated. Author

Quantitative feedback theory (QFT) has achieved the status as a very powerful design technique for the achievement of assigned performance tolerances over specific ranges of plant uncertainties without and with control effector failures. This paper presents a brief overview of QFT and its applications to advanced multi-input multi-output (MIMO) flight control systems. Desired performance over varied flight conditions may be achieved with fixed compensators (controllers), despite failures of effectors. QFT is the only design technique that has been able to make considerable progress in improving the design of an overall flight control system taking into account the man-in-the-loop specifications. ADAPTIVE RECONFIGURABLE FLIGHT CONTROLS FOR HIGH ANGLE OF ATTACK AIRCRAFT AGILITY

T. Sadeghi, M. Tascillo, A. Simons, and K. Lai *In* AGARD, Stability in Aerospace Systems Feb. 1993 13 p (For primary document see N94-11489 01-08)

Copyright Avail: CASI HC A03/MF A03

Two control technologies have been developed and integrated towards the definition of an Integrated Flight Control for the year 2000 (IFC2000) aircraft. The control technologies considered for IFC2000 are flight control reconfiguration and post stall maneuvering. The reconfiguration technique allows an aircraft to utilize the inherent redundancy among its control effectors for maintaining aircraft's controllability after loss (or degradation in effectiveness) of one or more of its control effectors. The reconfiguration technique used in this paper consisted of redistribution of control signals after identification of a control effector failure (first stage adaptation). This technique is based on utilizing a pseudo-inverse algorithm and minimizing a performance index to redistribute pilot's commands to the remaining control effectors. Two control laws were developed for controlling the aircraft in the post stall region where the aircraft is flying at high angle of attack (HAOA) while allowing reconfiguration in the event of surface damage or actuator failure. A self-tuning adaptive control law was developed for parameter estimation and control gain tuning (second stage adaptation). The control law utilizes the Bierman's algorithm for estimating aircraft parameters, and a linear quadratic regulator for tuning the gains. A neural net control law was developed to account for nonlinearity, parameter uncertainties, and disturbances in the flight control system. The reconfiguration, adaptive, and neural net control laws have been partially integrated; the results are reported in this paper. Post-stall maneuvering is configuration sensitive requiring a high performance aircraft with relaxed static stability, thrust vectoring, and/or additional surfaces (such as canard). A generic high performance aircraft model was modified to incorporate thrust vectoring for generating pitch and yaw moments. A control structure was developed to fly the aircraft with high angle of attack at low speed. The control structure can track alpha, phi, and beta commands from pilot's longitudinal and lateral sticks and rudder pedal, respectively. The control laws were designed to give steady state tracking for fuselage pointing. Thrust vectoring was used to produce pitch and yaw moments at HAOA. The control signal distribution function of the control laws was modified to facilitate aircraft transition from and to post-stall region. Author

TOWARD INTELLIGENT FLIGHT CONTROL

Robert F. Stengel *In* AGARD, Stability in Aerospace Systems Feb. 1993 22 p Sponsored in part by FAA (For primary document see N94-11489 01-08)
(Contract NGL-31-001-252; DAAL03-89-K-0092)
Copyright Avail: CASI HC A03/MF A03

Flight control systems can benefit by being designed to emulate functions of natural intelligence. Intelligent control functions fall in three categories: declarative, procedural, and reflexive. Declarative actions involve decision-making, providing models for system monitoring, goal planning, and system/scenario identification. Procedural actions concern skilled behavior and have parallels in guidance, navigation, and adaptation. Reflexive actions are more-or-less spontaneous and are similar to inner-loop control and estimation. Intelligent flight control systems will contain a hierarchy of expert systems, procedural algorithms, and computational neural networks, each expanding on prior functions to improve mission capability to increase the reliability and safety of flight and to ease pilot workload. IMPROVEMENT OF METHOD FOR EXPERIMENTAL DETERMINATION OF FLUTTER SPEED BY PARAMETER IDENTIFICATION Final Report

E. Nissim 5 Aug. 1993 7 p
(Grant NAGw-3201)
(NASA-CR-193555; NAS 1.26:193555) Avail: CASI HC A02/MF A01

The method investigated in the current research work is based on the identification of the equations of motion during test flights, followed by the solution of these identified equations to numerically compute the flutter dynamic pressure. The current research work is aimed at overcoming two main difficulties which arise when: (1) A continuous system is truncated into a system with a finite number of degrees of freedom. (2) The desired range of frequencies is wide; in the latter case, numerical difficulties occur that can only partly be overcome by giving relatively more weight to the high frequency modes. Results pertaining to the above first point will be presented under section entitled 'Truncation Effects', and results pertaining to the above second point will be presented under section entitled 'Frequency Range Effects'. The numerical example used herein consists of a continuous simply supported beam. It is further assumed that the object of the identification procedure is to identify the beam's first seven modes. DYNAMIC TESTER FOR ROTOR SEALS AND BEARINGS Patent

George L. vonPragenau, inventor (to NASA) 31 Aug. 1993 7 p Filed 1 Apr. 1991 Supersedes N91-25155 (29 - 17, p 2737)
(NASA-Case-MFS-28493-1; US-Patent-5,239,864; US-Patent-Appl-SN-678780; US-Patent-Class-73-118.1; US-Patent-Class-73-119R; US-Patent-Class-73-865.9; Int-Patent-Class-G01M-15/00; Int-Patent-Class-G01N-19/00) Avail: US Patent and Trademark Office

A dynamic tester for testing vibration damping seals and bearings is constructed having a hollow shaft extending through the seal or bearing, with the shaft internally supported at each end by fluid bearings on hollow bosses connected to an interior of an enclosure, with no rolling members connected to the shaft is described. A high pressure working fluid is forced through the hollow bosses to operate the bearings. Additionally, the shaft is provided with a reaction turbine that angularly vents a portion of the high pressure working fluid in order to rotate the shaft at high speed, up to 40,000 rpm. The seal or bearing is mounted in a bushing, in turn supported by rods to a shaking device that vibrates the seal or bearing as the shaft is rotated. A plurality of proximity sensors are mounted from outside the enclosure to sense shaft and seal bushing vibrations, and a plurality of pressure ports are disposed in the enclosure to allow sensing of dynamic and static pressures of the testing apparatus.

FLIGHT SIMULATOR EXPERIMENT OF THE COCKPIT ADVISORY SYSTEM [KOKKUPITTO ADOBAIZARI SHISUTEMU NO SHIMYURETA HYOUKA JIKKEN]

Keiji Tanaka, Hiroyasu Kawahara, Koutarou Matsumoto, and Hideo Masuzawa Apr. 1992 34 p In JAPANESE Original contains color illustrations

(NAL-TR-1151; JTN-93-80432; DE93-767975) Avail: CASI HC A03/MF A01

This paper describes the flight simulation experiment of a cockpit human-interface system which monitors aircraft utility systems and provides timely displays of aircraft conditions, warnings, and suggestions of initial actions, as well as operational procedures. This 'Cockpit Advisory System' is a kind of intelligent display which functions as a real-time flight manual. The current system was developed using the utility systems of 'ASKA', a Short Take-Off and Landing (STOL) experimental aircraft of the National Aerospace Laboratory (NAL). The system has two displays controlled by a real-time expert system, i.e., one for conditions and procedures and the other for various messages. Two pilots participated in flight simulator tests in which various emergency situations were encountered. Results indicate that the system: (1) remarkably reduced pilot workload; (2) enhanced crew coordination and situation awareness due to looking at color graphic displays instead of reading written checklists; (3) created a different cockpit environment since reading checklists is not necessary; and (4) is proved to be especially useful for pilot training. IMPROVEMENT OF THE FLOW QUALITY IN THE ARA TRANSONIC TUNNEL BY MEANS OF A LONG CELL HONEYCOMB

D. R. Stanniland, C. A. McHugh, and J. E. Green Aug. 1992 13 p Presented at the Conference on Wind Tunnels and Wind Tunnel Test Techniques, Southampton, England, 14-17 Sep. 1992 Original contains color illustrations
(ARA-Memo-375) Avail: CASI HC A03/MF A01

In August 1990, the flow smoothing screen in the ARA 9' x 8' Transonic Wind Tunnel was replaced by a honeycomb with a high ratio of cell length to diameter. Investigations into a suitable honeycomb design is described and the resulting changes in flow quality in the wind tunnel are presented. Detailed surveys of the total pressure, steady and unsteady flow angularity, and turbulence show that a high degree of flow uniformity was achieved in the test section. Turbulence levels of 0.05 percent longitudinally and 0.18 percent laterally were derived from measurements in the working section. These are in good agreement with values derived from settling chamber measurements and compare well with the estimates of minimum longitudinal and lateral turbulence levels (0.06 percent and 0.15 percent) achievable with the chosen design of honeycomb. Author (revised)

ARCJET EXPLORATORY TESTS OF ARC OPTICAL WINDOW DESIGN FOR THE AFE VEHICLE Final Report, 14 Dec. 1990 - 6 Mar. 1991

Ellis E. Whiting (Eloret Corp., Moffett Field, CA.), Imelda Terrazas-Salinas (Eloret Corp., Moffett Field, CA.), Roger A. Craig (Eloret Corp., Moffett Field, CA.), Charles K. Sobeck, George L. Sarver, III, Louis J. Salerno, Wendell Love, Scott Maa, and Al Covington Apr. 1991 86 p
(Contract NCC2-653)
(NASA-CR-192655; NAS 1.26:192655; AFE-9004-003) Avail: CASI HC A05/MF A01

Tests were made in the 20 MW arc jet facility at the NASA ARC to determine the suitability of sapphire and fused silica as window materials for the Aeroassist Flight Experiment (AFE) entry vehicle. Twenty nine tests were made; 25 at a heating rate about 80 percent of that expected during the AFE entry and 4 at approximately the full, 100 percent AFE heating rate profile, that produces a temperature of about 2900 F on the surface of the tiles that protect the vehicle. These tests show that a conductively cooled window design using mechanical thermal contacts and sapphire is probably not practical. Cooling the window using mechanical thermal contacts produces thermal stresses in the sapphire that cause the window to crack. An insulated design using sapphire, that cools the window as little as possible, appears promising although some spectral data in the vacuum-ultra-violet (VUV) will be lost due to the high temperature reached by the sapphire. The surface of the insulated sapphire windows, tested at the 100 percent AFE heating rate, showed some slight ablation, and cracks appeared in two of three test windows. One small group of cracks were obviously caused by mechanical binding of the window in the assembly, which can be eliminated with improved design. Other cracks were long, straight, thin crystallographic cracks that have very little effect on the optical transmission of the window. Also, the windows did not fall apart along these crystallographic cracks when the windows were removed from their assemblies. Theoretical results from the thermal analysis computer program SINDA indicate that increasing the window thickness from 4 to 8 mm may enable surface ablation to be avoided. An insulated design using a fused silica window tested at the nominal AFE heating rate experienced severe ablation, thus fused silica is not considered to be an acceptable window material. DEVELOPMENT OF MICROSTRIP GAS CHAMBER AND APPLICATION TO IMAGING GAMMA-RAY DETECTOR

T. Tanimori, S. Minami (Tokyo Inst. of Tech., Japan.), T. Nagae, T. Takahashi, and T. Miyagi Jul. 1992 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-754294; INS-939) Avail: Issuing Activity (Department of Energy (DOE))

Microstrip Gas Chamber (MSGC) was developed by using Multi-Chip technology which enables high-density assembly of bare Large Scale Integration (LSI) chips on a silicon board. Our MSGC was operated steadily with approximately 10(exp 3) gain more than one week. An energy resolution of 15% (FWHM) for 5.9 keV x-ray of Fe-55 was obtained. With very thin polyimide substrate of 16 microns thickness, two interesting phenomena were observed; one is a strong dependence of gains on the back plane potential, and the other is little time variation of gains. New type of MSGC with a guarding mask of a thin polyimide layer on the cathode edges was examined to reduce incidental electrical discharges between anode and cathode strips. Furthermore, a new approach to reduce the resistivity of the substrate was examined. By these approaches, the stability of the high gain operation of approximately 10(exp 4) was drastically improved. In addition, the possibility of the application of MSGC to the coded mask x-ray imaging detector for astrophysics is discussed. DOE

OVERVIEW OF THE 1989 WIND TUNNEL CALIBRATION WORKSHOP

Arthur Henderson, Jr. (Futron Corp., Washington, DC.) and L. Wayne McKinney Aug. 1993 45 p Workshop held in Hampton, VA, 19-20 Apr. 1989
(NASA-TP-3393; NAS 1.60:3393) Avail: CASI HC A03/MF A01

An overview of the 1989 Wind Tunnel Calibration Workshop held at NASA LaRC in Hampton, VA on 19-20 Apr. 1989 is presented. The purpose of the Workshop was to explore wind tunnel calibration requirements as they relate to test quality and data accuracy, with the ultimate goal of developing wind tunnel calibration requirements for the major NASA wind tunnels at ARC, LaRC, and LeRC. The two sessions addressed the following topics: (1) what constitutes a properly calibrated wind tunnel; and (2) the status of calibration of NASA's major wind tunnels. The most significant contributions to the stated goals are highlighted, and the consensus of the Workshop's conclusions and recommendations regarding formulation and implementation of that goal are presented. A UNIQUE FACILITY TO SUPPORT CRYOGENIC WIND TUNNEL OPERATIONS

R. Porter Sep. 1992 11 p Presented at the Conference on Wind Tunnels and Wind Tunnel Test Techniques, Southampton, England, 14-17 Sep. 1992
(ARA-Memo-377) Avail: CASI HC A03/MF A01

The cryogenic environmental room at Aircraft Research Association (ARA) is designed to support research activities related to the design of cryogenic wind tunnel models and to provide a means of checking out a fully instrumented wind tunnel model, at relatively low cost in preparation for a test campaign at cryogenic temperatures. The facility is essentially a large thermally insulated room which houses a low speed open return wind tunnel circuit. Cooling is achieved by the direct injection of liquid nitrogen into the circuit. A centrifugal fan generates moderate forced convection velocities of up to 10 m/s over a model which is located in the exit section of the circuit. The room is constructed in a modular form such that modifications can readily be performed and the tunnel circuit can be reconfigured for alternative working section arrangements. The installation of the environmental room and associated systems is complete and a commissioning phase is at an advanced stage. To date, the facility has been successfully operated at temperatures down to 123K. Author

THREE-DIMENSIONAL FINITE ELEMENT ANALYSIS OF EXPLOSIVE SAFETY FACILITIES: A TECHNOLOGY ASSESSMENT Interim Report, FY90 - FY92
T. A. Shugar, T. J. Holland, L. J. Malvar, and D. A. Doi Dec. 1992 152 p
(AF Proj. RM3-3-F-60)
(AD-A265700; NCEL-TN-1856) Avail: CASI HC A08/MF A02

To establish research requirements for the development of modern, specialized software for computational structural dynamics in support of Navy explosive safety facilities, NCEL conducted baseline studies to assess commercial or currently available general purpose computer programs. Two widely available general purpose computer programs for three-dimensional nonlinear dynamic finite element analysis were applied to three types of reinforced concrete structures of interest to Navy explosive safety facility designers: (1) a novel cylindrical missile test cell concept; (2) flat slabs with variable shear steel; and (3) a soil-covered roof slab for a new high performance magazine concept. Results from codified single-degree-of-freedom (SDOF) methods for design of explosive safety structures were also considered and compared with finite element technology. This report provides an overview of these baseline studies. DTIC

From the early 1960's, European governments were aware that they had to take part in the exploration, and potential exploitation, of space, or be left behind in a field of high-technology that had far-reaching possibilities. It was also realized that financial and manpower constraints would limit the extent to which individual nations could carry out their own national programs. They, therefor, joined forces in two organizations: the European Space Research Organization (ESRO) and the European Launcher Development Organization (ELDO). By 1975, when the potential of space development had been more fully appreciated, the two organizations were merged into the Europeans Space Agency (ESA) of which Spain was a founding member. ESA looks after the interest of 13 member states, one associated member state (Finland), and one cooperating state (Canada) in the peaceful uses of space. Its programs center around a mandatory core of technological research and space science to which member states contribute on the basis of their Gross National Product. Spain in 1992 contributes 6.46% to this mandatory program budget. The member states then have the chance to join optional programs that include telecommunications, observation of the earth and its environment, space transportation systems, microgravity research, and participation in the European contribution to the International Space Station Freedom. Each government decides whether it is in its interest to join a particular optional program, and the percentage that it wishes to contribute to the budget. Although in the early days of ESA, Spain participated in only a few optional programs, today Spain makes a significant contribution to nearly all of ESA's optional programs. This document presents Spain's contributions to particular ESA Programs and discusses Spain's future involvement in ESA. Derived from text

SATORI: SITUATION ASSESSMENT THROUGH THE RE-CREATION OF INCIDENTS Final Report
Mark D. Rodgers and Duane A. Duke Jul. 1993 13 p
(DOT/FAA/AM-93/12) Avail: CASI HC A03/MF A01

A system was developed that graphically re-creates the radar data recorded at En Route air traffic control (ATC) facilities. Each facility records data sent to the displays associated with the airspace under its control on a System Analysis Report (SAR) tape. SATORI (Situation Assessment Through Re-creation of Incidents) overlays the SAR data on the appropriate sector maps using map data from the Adaptation Control Environmental System (ACES) database. The analog switch display settings of the plan view display (PVD) are not recorded; however, subroutines were written for SATORI that allow the display to be set up with the settings reported to have been used by a given controller. In addition, SATORI has the capability to display the high and low weather intensity that was displayed on a given PVD. All software routines written for SATORI use Open Systems Foundation (OSF) technology. Similar data to those available from En Route facilities are recorded at Terminal Radar Approach Control (TRACON) facilities and should allow for the development of a re-creation tool much like the one discussed. Once SATORI is developed and evaluated, it will be possible to accomplish the goals of evaluating system designs, over-the-shoulder appraisals, training outcomes, procedures, airspace design, and measuring controller performance. Not only will the capabilities and features of SATORI provide those interested in air traffic with a valuable tool for assessing the dynamics of the air traffic situation, but additionally, and more importantly, the Agency will be in a better position to bring about effective change in future ATC systems. TOPEX ORBIT DETERMINATION USING GPS TRACKING SYSTEM Ph.D. Thesis
Hyung Jin Rim 1992 243 p
Avail: Univ. Microfilms Order No. DA9309265

An extensive simulation study was performed to analyze several aspects of Topex Precise Orbit Determination (POD) using the Global Positioning System (GPS). Since the error modeling is the key to such an experiment, extensive investigation was performed based on real GPS data processing experience to create realistic measurement and dynamic error models for GPS. Double-differenced Topex-GPS phase measurements were evaluated in relation to improving the Earth geopotential model, which is the dominant error source for Topex POD. The effect of model errors on the Topex orbit and gravity recovery accuracies was evaluated. Long arc and short arc gravity solutions were compared to understand the effect of the model errors in using the long arc and the short arc solutions for the gravity recovery. Limiting factors for the long arc and the short arc gravity recovery were identified. The effect of ambiguity parameters on the gravity recovery was analyzed. Since the number of ambiguity parameters are quite large, an algorithm was developed to handle the ambiguity parameters more efficiently. Subarc parameters and empirical parameters were tested to find an optimal set of parameters to be estimated for the gravity recovery. Several gravity models were obtained by combining Topex-GPS information with a nominal geopotential information. These combined gravity models were evaluated by the statistical comparison of the recovered geopotential model parameters and by the Topex orbit analysis. Significant improvement in the nominal geopotential model, especially for the low degree harmonics, was achieved. More than a factor of three improvement in Topex orbit accuracy was demonstrated using the recovered gravity model. Analysis associated with predicted Topex radial orbit errors using the solution covariance indicates error estimates for the orbit accuracy is realistic.

SATELLITE SITUATION REPORT, VOLUME 31, NO. 4

31 Dec. 1991 353 p

(NASA-TM-109232; NAS 1.15:109232) Avail: CASI HC A16/MF A03

This report consists of data computed at the U.S. Space Command, GSFC, or provided by satellite owners. A space objects box score table is presented with data under the following headings: source/organization, objects in orbit, and decayed objects. The objects in orbit and decayed objects headings have payload, debris, and total as subheadings. The bulk of the document is objects-in-orbit tables with data under the following headings: international designation, name, catalog number, source, launch date, period minutes, inclination, apogee (km), perigee (km), and notes.

A COMPARATIVE STUDY OF FULL NAVIER-STOKES AND REDUCED NAVIER-STOKES ANALYSES FOR SEPARATING FLOWS WITHIN A DIFFUSING INLET S-DUCT

B. H. Anderson, D. R. Reddy, and K. Kapoor Jun. 1993 18 p Presented at the 29th AIAA Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE

(RTOP 505-62-52)

(NASA-TM-106250; E-7972; NAS 1.15:106250; AIAA Paper 93-2154)

Avail: CASI HC A03/MF A01

A three-dimensional implicit Full Navier-Stokes (FNS) analysis and a 3D Reduced Navier-Stokes (RNS) initial value space marching solution technique has been applied to a class of separate flow problems within a diffusing S-duct configuration characterized as vortex-liftoff. Both Full Navier-Stokes and Reduced Navier-Stokes solution techniques were able to capture the overall flow physics of vortex lift-off, however more consideration must be given to the development of turbulence models for the prediction of the locations of separation and reattachment. This accounts for some of the discrepancies in the prediction of the relevant inlet distortion descriptors, particularly circumferential distortion. The 3D RNS solution technique adequately described the topological structure of flow separation associated with vortex lift-off.

ACHIEVEMENTS AND CHALLENGES OF SPACE STATION FREEDOM'S SAFETY REVIEW PROCESS

David W. Robinson Jul. 1993 17 p Proposed for presentation at the 11th International System Safety Conference, Cincinnati, OH, 28 Jul. - 2 Aug. 1993; sponsored by the System Safety Society

(RTOP 474-17-10)

(NASA-TM-106199; E-7959; NAS 1.15:106199) Avail: CASI HC A03/MF A01

The most complex space vehicle in history, Space Station Freedom, is well underway to completion, and System Safety is a vital part of the program. The purpose is to summarize and illustrate the progress that over one-hundred System Safety engineers have made in identifying, documenting, and controlling the hazards inherent in the space station. To date, Space Station Freedom has been reviewed by NASA's safety panels through the first six assembly flights, when Freedom achieves a configuration known as Man Tended Capability. During the eight weeks of safety reviews spread out over a year and a half, over 200 preliminary hazard reports were presented. Along the way NASA and its contractors faced many challenges, made much progress, and even learned a few lessons. Author

INVESTIGATION OF MULTIPHASE RAILGUN SYSTEMS Ph.D. Thesis

Sunil Keshava Murthy 1992 206 p

Avail: Univ. Microfilms Order No. DA9309240

Multiphase railguns (electromagnetic launchers) powered by multiphase compensated pulsed alternators (compulsators) is examined. The impediments to implementing multiphase railguns are identified and solutions to the problems are presented. Methods for improving the acceleration profile of the multiphase railgun system are also detailed. Several options of a single element multiphase compulsator powered railgun system are discussed. Comparison of the multiphase railgun system with the existing state of the art single phase compulsator driven railgun system is also included. Dissert. Abstr.

This report explains the procedural anomaly that occurred during the launch sequence of an Orbital Sciences Corporation Pegasus expendable launch vehicle, which was subsequently deployed successfully from an NB-52B airplane, on 9 Feb. 1993. The safety issues discussed in the report include command, control and communications responsibility, launch crew fatigue, launch interphone procedures, efficiency of launch constraints, and the lack of common launch documents. Safety recommendations concerning these issues were made to the Department of Transportation, the National Aeronautics and Space Administration, and the Orbital Sciences Corporation. DEBRIS/ICE/TPS ASSESSMENT AND INTEGRATED PHOTOGRAPHIC ANALYSIS FOR SHUTTLE MISSION STS-57 Final Report, 18 Jun. - 2 Jul. 1993

Gregory N. Katnik, Barry C. Bowen, and J. Bradley Davis Jul. 1993 131 p Original contains color illustrations

(NASA-TM-107562; NAS 1.15:107562) Avail: CASI HC A07/MF A02; 47 functional color pages

A Debris/Ice/Thermal Protection System (TPS) assessment and integrated photographic analysis was conducted for Shuttle mission STS-57. Debris inspections of the flight elements and launch pad were performed before and after launch. Ice/frost conditions on the External Tank were assessed by the use of computer programs, nomographs, and infrared scanner data during cryogenic loading of the vehicle followed by on-pad visual inspection. High speed photography was analyzed after launch to identify ice/debris sources and evaluate potential vehicle damage and/or in-flight anomalies. The debris/ice/TPS conditions and integrated photographic analysis of Shuttle mission STS-57, and the resulting effect on the Space Shuttle Program are documented. Author (revised)

SPACE TRANSPORTATION ALTERNATIVES FOR LARGE SPACE PROGRAMS: THE INTERNATIONAL SPACE UNIVERSITY SUMMER SESSION, 1992

Bryan A. Palaszewski Jun. 1993 25 p Presented at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE

(RTOP 506-42-72)

(NASA-TM-106271; E-7999; NAS 1.15:106271; AIAA Paper 93-2278) Copyright Avail: CASI HC A03/MF A01

In 1992, the International Space University (ISU) held its Summer Session in Kitakyushu, Japan. This paper summarizes and expands upon some aspects of space solar power and space transportation that were considered during that session. The issues discussed in this paper are the result of a 10-week study by the Space Solar Power Program design project members and the Space Transportation Group to investigate new paradigms in space propulsion and how those paradigms might reduce the costs for large space programs. The program plan was to place a series of power satellites in Earth orbit. Several designs were studied where many kW, MW, or GW of power would be transmitted to Earth or to other spacecraft in orbit. During the summer session, a space solar power system was also detailed and analyzed. A high-cost space transportation program is potentially the most crippling barrier to such a space power program. At ISU, the focus of the study was to foster and develop some of the new paradigms that may eliminate the barriers to low cost for space exploration and exploitation. Many international and technical aspects of a large multinational program were studied. Environmental safety, space construction and maintenance, legal and policy issues of frequency allocation, technology transfer and control and many other areas were addressed. Over 120

students from 29 countries participated in this summer session. The results discussed in this paper, therefore, represent the efforts of many nations.

TRANSPORTATION SYSTEMS ANALYSES: VOLUME 1: EXECUTIVE SUMMARY Semiannual Report
6 May 1993 21 p
(Contract NAS8-39209)
(NASA-CR-192583; NAS 1.26:192583) Avail: CASI HC A03/MF A01

The principal objective of this study is to accomplish a systems engineering assessment of the nation's space transportation infrastructure. This analysis addresses the necessary elements to perform man delivery and return, cargo transfer, cargo delivery, payload servicing, and the exploration of the Moon and Mars. Specific elements analyzed, but not limited to, include the Space Exploration Initiative (SEI), the National Launch System (NLS), the current expendable launch vehicle (ELV) fleet, ground facilities, the Space Station Freedom (SSF), and other civil, military and commercial payloads. The performance of this study entails maintaining a broad perspective on the large number of transportation elements that could potentially comprise the U.S. space infrastructure over the next several decades. To perform this systems evaluation, top-level trade studies are conducted to enhance our understanding of the relationships between elements of the infrastructure. This broad 'infrastructure-level perspective' permits the identification of preferred infrastructures. Sensitivity analyses are performed to assure the credibility and usefulness of study results. This executive summary of the transportation systems analyses (TSM) semi-annual report addresses the SSF logistics resupply. Our analysis parallels the ongoing NASA SSF redesign effort. Therefore, there could be no SSF design to drive our logistics analysis. Consequently, the analysis attempted to bound the reasonable SSF design possibilities (and the subsequent transportation implications). No other strategy really exists until after a final decision is rendered on the SSF configuration.

This report identifies trends in the volume and type of traffic offered to the U.S. domestic communications infrastructure and extrapolates these trends through the year 2011. To describe how telecommunications service providers are adapting to the identified trends, this report assesses the status, plans, and capacity of the domestic communications infrastructure. Cable, satellite, and radio components of the infrastructure are examined separately. The report also assesses the following major applications making use of the infrastructure: (1) Broadband services, including Broadband Integrated Services Digital Network (BISDN), Switched Multimegabit Data Service (SMDS), and frame relay; (2) mobile services, including voice, location, and paging; (3) Very Small Aperture Terminals (VSAT), including mesh VSAT; and (4) Direct Broadcast Satellite (DBS) for audio and video. The report associates satellite implementation of specific applications with market segments appropriate to their features and capabilities. The volume and dollar value of these market segments are estimated. For the satellite applications able to address the needs of significant market segments, the report also examines the potential of each satellite-based application to capture business from alternative technologies.

REMOTE SURFACE WATER MONITORING RADIO BASED TELEMETRY SYSTEM
W. L. Goodwin and D. Baxter Feb. 1993 12 p Presented at the Thematic Conference of Geologic Remote Sensing, Pasadena, CA, 15 Mar. 1993
(Contract DE-AC34-90DP-62349)
(DE93-009643; RFP-4718; CONF-9303121-1) Avail: CASI HC A03/MF A01

The Environmental Protection Department of EG&G Rocky Flats has designed and developed a unique Remote Surface Water Monitoring System using radio telemetry hardware and computer control software. The system is based on new technologies in microelectronics and environmental monitoring sensors. An engineering team, headed up by the Surface Water Division at EG&G, has proven that with careful evaluation of new technologies and hardware components, a reliable, cost effective and graphical user interface (GUI) system can be designed and installed. The network utilizes standard industrial control hardware and off-the-shelf components in order to meet several time requirements outlined by an Interagency Agreement (IAG) between the Department of Energy, the U.S. Environmental Protection Agency, and state and local authorities. In addition, the system had to meet tight environmental specifications and procedures. The Rocky Flats Plant is part of the U.S. Department of Energy Weapons Complex and is located near the Denver metropolitan area. The plant is required by law, and Interagency Agreement, to maintain strict environmental standards for surface water monitoring and discharge characteristics, including the requirement for utilization of best available technology. ESTIMATION OF THE ATTITUDE MOTION OF THE SMALL SATELLITE ORIZURU [KOGATA JIKKEN EISEI ORIZURU NO SHISEI UNDOU]

Atsushi Nakajima, Fuyuto Terui, Kazuto Ishii, and Hiroaki Habe Apr. 1992 31 p In JAPANESE

(NAL-TR-1145; JTN-93-80437) Avail: CASI HC A03/MF A01

The attitude motion of the small experimental satellite, ORIZURU, was estimated by comparing flight data with computer simulation results from its dynamic model. ORIZURU was ejected from the 2nd stage of an H-1 launch vehicle by a separation mechanism having a single coil-spring whose mechanical characteristics possess a certain degree of uncertainty. Since ORIZURU only transmits attitude information using its sun sensors, both the initial angular momentum added to the satellite at separation from the launcher and its steady motion during in-orbit experimentation were estimated to evaluate release mechanism characteristics and to perform experimental data analysis. EXERGY DECREASE IN SHOCK WAVES AND BOUNDARY LAYERS OF SPACE LAUNCH VEHICLES M.S. Thesis

Benjamin F. Roper Mar. 1993 61 p

(AD-A265272) Avail: CASI HC A04/MF A01

The exergy method of analysis uses both the First and Second laws of Thermodynamics to determine where losses occur. This method has been shown to be superior to conventional heat balance analyzes. A primary contributor to the exergy decrease is the production of entropy. Entropy is produced in shock waves and boundary layers, as well as in other regions of the flowfield. A method of analysis is presented to quantify the entropy that is produced in the bow shock wave and the boundary layer of a space launch vehicle for Mach numbers between 1.1 and 10. DTIC

PROTON TRANSPORT METHODS FOR SATELLITE SHIELD MODELING

C. R. Drumm Mar. 1993 45 p

(Contract DE-AC04-76DP-00789)

(DE93-013602; SAND-93-0200) Avail: CASI HC A03/MF A01

Satellite electronics may be subjected to a large fluence of protons from the Van Allen belt and from solar flares. To determine if unhardened electronics will survive a radiation environment, the total ionizing dose and displacement damage to the electronics must be determined. Several computer codes are available for modeling proton transport. The codes range in complexity from a very-efficient straight-line approximation to general-geometry, time-dependent Monte Carlo transport, with corresponding increase in computer run time. For most satellite applications, neutrons can be neglected in the analysis. However, neutrons may be important for modeling heavily shielded compartments for personnel and electronics. DOE

SPACE STATION REDESIGN TEAM: FINAL REPORT TO THE ADVISORY COMMITTEE ON THE REDESIGN OF THE SPACE STATION

Jun. 1993 300 p

(NASA-TM-109241; NAS 1.15:109241) Avail: CASI HC A13/MF A03

This report is the result of the Space Station Redesign Team's activity. Its purpose is to present without bias, and in appropriate detail, the characteristics and cost of three design and management approaches for the Space Station Freedom. It was presented to the Advisory Committee on the Redesign of the Space Station on 7 Jun. 1993, in Washington, D.C. Derived from text

DIMENSIONAL SCALING FOR IMPACT CRATERING AND PERFORATION

Alan Watts, Dale Atkinson, and Steve Rieco 16 Mar. 1993 174 p

Sponsored by NASA. Johnson Space Center

(NASA-CR-188259; NAS 1.26:188259) Avail: CASI HC A08/MF A02

This report summarizes the development of two physics-based scaling laws for describing crater depths and diameters caused by normal incidence impacts into aluminum and TFE Teflon. The report then describes equations for perforations in aluminum and TFE Teflon for normal impacts. Lastly, this report also studies the effects of non-normal incidence on cratering and perforation. THE MAGNITUDE OF IMPACT DAMAGE ON LDEF MATERIALS Final Report
Martha Allbrooks and Dale Atkinson 11 Jul. 1992 89 p Original contains color illustrations
(Contracts NAS9-17900; SC-02N0165768; POD Proj. 960-12-171)
(NASA-CR-188258; NAS 1.26:188258) Avail: CASI HC A05/MF A01; 40 functional color pages

The purpose of this report is to document the magnitude and types of impact damage to materials and systems on the LDEF. This report will provide insights which permit NASA and industry space-systems designers to more rapidly identify potential problems and hazards in placing a spacecraft in low-Earth orbit (LEO). This report is structured to provide (1) a background on LDEF, (2) an introduction to the LEO meteoroid and debris environments, and (3) descriptions of the types of damage caused by impacts into structural materials, and contamination caused by spallation and ejecta from impact events. TOPEX/POSEIDON: A UNITED STATES/FRANCE MISSION. OCEANOGRAPHY FROM SPACE: THE OCEANS AND CLIMATE
1992 23 p Original contains color illustrations
(NASA-TM-108253; NAS 1.15:108253) Avail: CASI HC A03/MF A01; 17 functional color pages

The TOPEX/POSEIDON space mission, sponsored by NASA and France's space agency, the Centre National d'Etudes Spatiales (CNES), will give new observations of the Earth from space to gain a quantitative understanding of the role of ocean currents in climate change. Rising atmospheric concentrations of carbon dioxide and other 'greenhouse gases' produced as a result of human activities could generate a global warming, followed by an associated rise in sea level. The satellite will use radar altimetry to measure sea-surface height and will be tracked by three independent systems to yield accurate topographic maps over the dimensions of entire ocean basins. The satellite data, together with the Tropical Ocean and Global Atmosphere (TOGA) program and the World Ocean Circulation Experiment (WOCE) measurements, will be analyzed by an international scientific team. By merging the satellite observations with TOGA and WOCE findings, the scientists will establish the extensive data base needed for the quantitative description and computer modeling of ocean circulation. The ocean models will eventually be coupled with atmospheric models to lay the foundation for predictions of global climate change. Derived from text

EXPERIMENTAL MEASUREMENT OF THE PLASMA CONDUCTIVITY OF Z93 AND Z93P THERMAL CONTROL PAINT
G. Barry Hillard Sep. 1993 77 p
(RTOP 506-41-52)
(NASA-TM-106284; E-8022; NAS 1.15:106284) Avail: CASI HC A05/MF A01

Two samples each of Z93 and Z93P thermal control paint were exposed to a simulated space environment in a plasma chamber. The samples were biased through a series of voltages ranging from -200 volts to +300 volts and electron and ion currents measured. By comparing the currents to those of pure metal samples of the same size and shape, the conductivity of the samples was calculated. Measured conductivity was dependent on the bias potential in all cases. For Z93P, conductivity was approximately constant over much of the bias range and we find a value of 0.5 micro-mhos per square meter for both electron and ion current. For Z93, the dependence on bias was much more pronounced but conductivity can be said to be approximately one order of magnitude larger. In addition to presenting these results, this report documents all of the experimental data as well as the statistical analyses performed. Author

SPACE STATION REDESIGN OPTION A: MODULAR BUILDUP CONCEPT
10 Jun. 1993 85 p
(NASA-TM-108415; NAS 1.15:108415) Avail: CASI HC A05/MF A01

In early 1993, President Clinton mandated that NASA look at lower cost alternatives to Space Station Freedom. He also established an independent advisory committee - the Blue Ribbon Panel - to review the redesign work and evaluate alternatives. Daniel Goldin, NASA Administrator, established a Station Redesign Team that began operating in late March from Crystal City, Virginia. NASA intercenter teams - one each at Marshall Space Flight Center, Johnson Space Center, and Langley Research Center provided engineering and other support. The results of the Option A study done at Marshall Space Flight Center are summarized. Two configurations (A-1 and A-2) are covered. Additional data is provided in the briefing package MSFC SRT-001, Final System Review to SRT-002, Space Station Option A Modular Buildup Concept, Volumes 1-5, Revision B, June 10, 1993. In June 1993, President Clinton decided to proceed with a modular concept consistent with Option A, and asked NASA to provide an Implementation Plan by September. All data from the Option A redesign activity was provided to NASA's Transition Team for use in developing the Implementation Plan. Author (revised)

IN-ORBIT PERFORMANCE TESTS AND TELE-COMMAND SYSTEMS OF THE UMBRELLA TEST SATELLITE (DEBUT) ['ORIZURU' (DEBUT) NO UCHUU JIKKEN UNYOU]
Takao Kumagai, Atsushi Nakajima, and Yoshio Sakurai Jun. 1992 27 p In JAPANESE
(NAL-TR-1165; JTN-93-80445) Avail: CASI HC A03/MF A01

In February 1990, an H-1 launch vehicle was launched which successfully put DEBUT (Deployable Boom and Umbrella Test Satellite), MOS-1b (Marine Observation Satellite), and JAS-1b (Japan Amateur Radio Satellite) into each orbits. DEBUT is the small satellite (50 kg) having deployable and retractable boom and umbrella systems which are important subsystems to be used on the Tether/Boomeran Satellite. All the mission and telemetry/command (tele-command) systems functioned well, and all the planned, in-orbit performance tests were successfully completed. These tests and DEBUT's tele-command systems are described. Author (NASDA)

ANALYSIS OF GEOPHYSICAL MEASUREMENTS AND SPACECRAFT INTERACTIONS Final Report, Jun. 1989 - Jan. 1993
J. N. Bass, K. H. Bhavnani, N. A. Bonito, K. H. Bounar, and P. L. Grady 29 Jan. 1993 286 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-89-C-0068)
(AD-A266064; RXR-93011; PL-TR-93-2031) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Investigations were supported to analyze geophysical measurements with integrated applications of ephemerides physics and mathematics of the ionosphere and near space. The projects undertaken included analytical and computational simulation of the interactive spacecraft processes associated with the following: charging, contamination, liquid venting, and critical ionization velocity; data based and analytical investigations of trapped particles, dosage, magnetic fields, and instrumentation for the CRRES experiment; and data based studies of auroral electron and ion precipitation including neural network techniques, ionospheric scintillation and OTH backscatter, and atmospheric density and orbital decay. Systems were developed and applied for calibration and processing of the CRRES and APEX magnetometers, and for generation of satellite attitude and ephemeris. Techniques employed for applying coordinate systems, depicting vehicle and astronomical circumstances, and interactively presenting data in conventional and color formats are also described. DTIC

N94-11223# Weight (Thomas H.) and Associates, Long Beach, CA.
FUZZIFICATION OF ASAT'S RULE BASED AIMPOINT SELECTION Final Report, 2 Nov. 1992 - 15 Jun. 1993
Thomas H. Weight 15 Jun. 1993 69 p
(Contract DASG60-93-C-0005)
(AD-A266068) Avail: CASI HC A04/MF A01

The aimpoint algorithms being developed at Dr. Weight and Associates are based on the concept of fuzzy logic. This approach does not require a particular type of sensor data or algorithm type, but allows the user to develop a fuzzy logic algorithm based on existing aimpoint algorithms and models. This provides an opportunity for the user to upgrade an existing system design to achieve higher performance at minimal cost. Many projects have aimpoint algorithms which are based on 'crisp' logic rule based algorithms. These algorithms are sensitive to glint, corner reflectors, or intermittent thruster firings, and to uncertainties in the a priori estimates of angle of attack. If these projects are continued through to a demonstration involving a launch to hit a target, it is quite possible that the crisp logic approaches will need to be upgraded to handle these important error sources. ESRO'S FIRST SCIENTIFIC SATELLITE PROGRAMME, 1961 - 1966
M. DeMaria (Rome Univ., Italy.), J. Krige (European Univ. Inst., Florence, Italy.), and Arturo Russo (Palermo Univ., Italy.) Oct. 1992 51 p Original contains color illustrations
(ESA-HSR-2) Avail: CASI HC A04/MF A01

The European Space Agency (ESA) History Study Reports are preliminary reports of studies carried out within the framework of an ESA contract. As such they will form the basis of a comprehensive study of European Space activities covering the period from 1959 to 1987. The early development of ESRO's satellite program is addressed. The process which led to the definition of ESRO's eight year scientific program is analyzed. The organizational structure by which proposals coming from the scientific community were discussed within ESRO in order to arrive at definite choices about mission objectives and satellite payloads is described. The painful process of revision of the original program undertaken in the first three-year period of ESRO (1964-1966) is addressed. Derived from text

PROJECT OF AN ATTITUDE CONTROL SYSTEM (THREE AXIS) OF A SATELLITE USING THE LQG/LTR METHODOLOGY M.S. Thesis [PROJETO DE UM SISTEMA DE CONTROLE DE ATITUDE (TRES EIXOS) DE SATELITES UTILIZANDO A METODOLOGIA LQG/LTR]
Ney Ricardo Moscati Feb. 1992 239 p In PORTUGESE
(INPE-5473-TDI/504) Avail: CASI HC A11/MF A03

In Earth remote sensing satellites, an Attitude Control System (ACS) is necessary for stabilization, due to the fact that even if the vehicle is precisely oriented in launch, it can deviate from this orientation due the influence of ambiental torques, internal changes and coupling between attitude dynamics and a satellite's orbital and flexible dynamics. The configuration adopted for the ACS (a momentum wheel and two reaction wheels) exhibits a strong coupling between roll and yaw, hence it is a multivariable system, while the pitch axis is practically decoupled. The linear model for the attitude dynamics of this satellite exhibits uncertainties due to non-modeled dynamics of the flexible panels and giroscopic coupling variations, caused by momentum wheel velocity changes. The LQG/LTR methodology is used to project the ACS operating on the normal mode. This methodology is inherently a multivariable tool, where the compensator's structure is known as MBC, the same structure as LQG compensators. It is based on both time and frequency domain approaches, and has the great advantage of treating the robustness at project level. The frequency project specifications, usually used for SISO systems such as gain and phase margins, bandwidth, disturbance rejection characteristics and insensitivity to parameter variations are extended to the MIMO case through the singular value concept. The LQG/LTR methodology provides, basically, the recovery of the excellent robustness characteristics of systems with LQR regulators when the state is completely measured. On the other hand, specifications on the time domain are difficult to deal with. In view of the easy usage of the methodology and good simulations results obtained, it has been concluded that the LQG/LTR methodology is an attractive option to project ACS when the model is a MIMO type. LESSONS LEARNED FROM THE LONG DURATION EXPOSURE FACILITY
Wayne K. Stuckey 15 Feb. 1993 20 p
(Contract F04701-88-C-0089)
(AD-A266026; TR-93(3935)-7; SMC-TR-93-23) Avail: CASI HC A03/MF A01

The Long Duration Exposure Facility (LDEF) was launched by the Space Shuttle in Apr. 1984 and recovered in Jan. 1990. There were 57 experiments containing over 10,000 specimens to test the effects of the space environment on materials, components, and systems. Originally planned for one year, the exposure actually lasted almost six years. While many LDEF investigations are continuing, results to date have given valuable information on long-term performance in orbit. Results from the LDEF investigators and the Special Investigation Groups are briefly summarized along with potential benefits from LDEF for future missions. DTIC

SPACE TRUSS ZERO GRAVITY DYNAMICS Final Report, Mar. 1989 - Feb. 1990
Andrew D. Swanson, Wayne Yuen, and John R. Mackaman Mar. 1993 49 p
(AF Proj. 2401)
(AD-A266130; WL-TR-92-3030) Avail: CASI HC A03/MF A01

This technical report describes two truss experiments flown on the NASA KC-135 Reduced Gravity Aircraft. The purpose of these experiments was to investigate large space structure dynamics, ground test methods, and passive and active damping. A 2-meter truss was first flown to determine the rigid body dynamics in the aircraft during zero-gravity. The second flight's objective was to measure structural modes of a 12-meter truss, which represented a space structure component. Typically five to ten seconds of zero gravity data were recorded for each parabolic arc. Flight test results are compared with ground testing in which a low restraint spring mechanism was used to suspend the truss. Good correlation between ground and flight test results was achieved; the major differences were caused by suspension system friction, which coupled the frame modes with the bending and torsion modes. Nuclear Element Tests (NET) which are being performed as part of the US Air Force Space Nuclear Thermal Propulsion (SNTP) Program to evaluate high performance fuel elements intended for use in future nuclear propulsion systems are described. The NET experiments are to be performed at the Sandia National Laboratories (SNL's) Annular Core Research Reactor (ACRR). Objectives of these experiments are to provide engineering validation and demonstration of critical-fuel-element-related technologies and an experimental data base to support analytical design methods for the SNTP Program. Currently, hardware for the first two fueled NET experiments was fabricated, and cold flow tests were accomplished with a representative set of hardware to assure the experimental capability to achieve test objectives in-reactor. Assembly of the first NET experiment to test a representative nuclear fuel elements is in progress, and planned operational sequences were defined. DOE

Electrically powered arc jets which produce thrust at high specific impulse could provide a substantial cost reduction for orbital transfer and station keeping missions. There is currently a limited understanding of the complex, nonlinear interactions in the plasma propellant which has hindered the development of high efficiency arc jet thrusters by making it difficult to predict the effect of design changes and to interpret experimental results. A computational model developed at the University of Tennessee Space Institute (UTSI) to study laser powered thrusters and radio frequency gas heaters has been adapted to provide a tool to help understand the physical processes in arc jet thrusters. The approach is to include in the model those physical and chemical processes which appear to be important, and then to evaluate our judgement by the comparison of numerical simulations with experimental data. The results of this study have been presented at four technical conferences. The details of the work accomplished in this project are covered in the individual papers included in the appendix of this report. We present a brief description of the model covering its most important features followed by a summary of the effort. Derived from text

CHARACTERIZATION OF IN-FLIGHT PERFORMANCE OF ION PROPULSION SYSTEMS
James S. Sovey and Vincent K. Rawlin Jun. 1993 15 p Presented at the 29th AIAA Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE
(RTOP 506-42-31)
(NASA-TM-106283; E-8021; NAS 1.15:106283; AIAA Paper 93-2217)
Avail: CASI HC A03/MF A01

In-flight measurements of ion propulsion performance, ground test calibrations, and diagnostic performance measurements were reviewed. It was found that accelerometers provided the most accurate in-flight thrust measurements compared with four other methods that were surveyed. An experiment has also demonstrated that pre-flight alignment of the thrust vector was sufficiently accurate so that gimbal adjustments and use of attitude control thrusters were not required to counter disturbance torques caused by thrust vector misalignment. The effects of facility background pressure, facility enhanced charge-exchange reactions, and contamination on ground-based performance measurements are also discussed. Vacuum facility pressures for inert-gas ion thruster life tests and flight qualification tests will have to be less than 2 mPa to ensure accurate performance measurements. Author

AXISYMMETRIC SINGLE SHEAR ELEMENT COMBUSTION INSTABILITY EXPERIMENT
Kevin J. Breisacher Jun. 1993 13 p Presented at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE
(RTOP 584-03-11)
(NASA-TM-106327; E-8082; NAS 1.15:106327; AIAA Paper 93-1953)
Avail: CASI HC A03/MF A01

The combustion stability characteristics of a combustor consisting of a single shear element and a cylindrical chamber utilizing LOX and gaseous hydrogen as propellants are presented. The combustor geometry and the resulting longitudinal mode instability are axisymmetric. Hydrogen injection temperature and pyrotechnic pulsing were used to determine stability boundaries. Mixture ratio, fuel annulus gap, and LOX post configuration were varied. Performance and stability data are presented for chamber pressures of 300 and 1000 psia. Author

SPECIFICATION AND TESTING FOR POWER BY WIRE AIRCRAFT
Irving G. Hansen and Barbara H. Kenney Aug. 1993 8 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993; sponsored by American Chemical Society
(RTOP 538-01-11)
(NASA-TM-106232; E-7951; NAS 1.15:106232) Avail: CASI HC A02/MF A01

A power by wire aircraft is one in which all active functions other than propulsion are implemented electrically. Other nomenclature are 'all electric airplane,' or 'more electric airplane.' What is involved is the task of developing and certifying electrical equipment to replace existing hydraulics and pneumatics. When such functions, however, are primary flight controls which are implemented electrically, new requirements are imposed that were not anticipated by existing power system designs. Standards of particular impact are the requirements of ultra-high reliability, high peak transient bi-directional power flow, and immunity to electromagnetic interference and lightning. Not only must the electromagnetic immunity of the total system be verifiable, but box level tests and meaningful system models must be established to allow system evaluation. This paper discusses some of the problems, the system modifications involved, and early results in establishing wiring harness and interface susceptibility requirements. Author (revised)

INVESTIGATION OF ALTERNATE POWER SOURCE FOR SPACE SHUTTLE ORBITER HYDRAULIC SYSTEM Final Technical Report
William E. Simon and Fred M. Young 26 May 1993 95 p
(Grant NAG9-626)
(NASA-CR-193229; NAS 1.26:193229) Avail: CASI HC A05/MF A01

This investigation consists of a short-term feasibility study to determine whether or not an alternate electrical power source would trade favorably from a performance, reliability, safety, operation, and weight standpoint in replacing the current auxiliary power unit subsystems with its attendant components (water spray boiler, hydrazine fuel and tanks, feed and vent lines, controls, etc.), operating under current flight rules. Results of this feasibility study are used to develop recommendations for the next step (e.g., to determine if such an alternate electrical power source would show an advantage given that the current operational flight mode of the system could be modified in such a way as not to constrain the operational capability and safety of the vehicle). However, this next step is not within the scope of this investigation. This study does not include a cost analysis, nor does it include investigation of the integration aspects involved in such a trade, except in a qualitative sense for the determination of concept feasibility. A three-dimensional, time dependent, Favre averaged, finite volume Navier-Stokes code has been developed to model compressible and incompressible flows (with and without chemical reactions) in liquid rocket engines. The code has a non-staggered formulation with generalized body-fitted-coordinates (BFC) capability. Higher order differencing methodologies such as MUSCL and Osher-Chakravarthy schemes are available. Turbulent flows can be modeled using any of the five turbulent models present in the code. A two-phase, two-liquid, Lagrangian spray model has been incorporated into the code. Chemical equilibrium and finite rate reaction models are available to model chemically reacting flows. The discrete ordinate method is used to model effects of thermal radiation. The code has been validated extensively against benchmark experimental data and has been applied to model flows in several propulsion system components of the SSME and the STME. Author

SPACE STORABLE ROCKET TECHNOLOGY PROGRAM (SSRT). OPTION 1 PROGRAM Final Report
Melvin L. Chazen, Thomas Mueller, and Thomas Rust 5 Aug. 1993

95 p
(Contract NAS3-26246)
(NASA-CR-191171; NAS 1.26:191171) Avail: CASI HC A05/MF A01

The Space Storable Rocket Technology (SSRT) Option 1 Program was initiated in October 1991 after completion of the Basic Program. The program was restructured in mid-July 1992 to incorporate a Rhenium Technology Task and reduce the scope of the LO2-N2H4 engine development. The program was also extended to late February 1993 to allow for the Rhenium Technology Task completion. The Option 1 Program was devoted to evaluation of two new injector elements, evaluation of two different methods of thermal protection of the injector, evaluation of high temperature material properties of rhenium and evaluation of methods of joining the rhenium thrust chamber to the columbium injector and nozzle extension. In addition, critical experiments were conducted (Funded by Option 2) to evaluate mechanisms to understand the effects of GO2 injection into the chamber, helium injection into the main LO2, effect of the splash plate and effect of decreasing the aspect ratio of the 120-slot (-13a) element. The performance and thermal models were used to further correlate the test results with analyses. The results of the work accomplished are summarized. Derived from text

Avail: CASI HC A03/MF A01

The application of fusion power to space propulsion requires rethinking the engineering-design solution to controlled-fusion energy. Whereas the unit cost of electricity (COE) drives the engineering-design solution for utility-based fusion reactor configurations; initial mass to low earth orbit (IMLEO), specific jet power (kW(thrust)/kg(engine)), and reusability drive the engineering-design solution for successful application of fusion power to space propulsion. We applied three design principles (DP's) to adapt and optimize three candidate-terrestrial-fusion-reactor configurations for propulsion in space. The three design principles are: provide maximum direct access to space for waste radiation, operate components as passive radiators to minimize cooling-system mass, and optimize the plasma fuel, fuel mix, and temperature for best specific jet power. The three candidate terrestrial fusion reactor configurations are: the thermal barrier tandem mirror (TBTM), field reversed mirror (FRM), and levitated dipole field (LDF). The resulting three candidate space fusion propulsion systems have their IMLEO minimized and their specific jet power and reusability maximized. We performed a preliminary rating of these configurations and concluded that the leading engineering-design solution to space fusion propulsion is a modified TBTM that we call the Mirror Fusion Propulsion System (MFPS). Control system design and design verification make use of a variety of simulation tools, often including both nonreal-time and hardware-in-the-loop simulation. Additionally, the design process often uses linear analysis tools. This paper discusses the use of frequency-response analysis to assist in verifying that the different design and verification tools are consistent, and to help uncover and understand inconsistancies should they exist. The control system design example considered is for an elastic sounding-rocket thrust-vector control system. DOE

A small laboratory diagnostic thruster was developed to augment present low thrust chemical rocket optical and heat flux diagnostics at the NASA Lewis Research Center. The objective of this work was to evaluate approaches for the use of temperature and pressure sensors for the investigation of low thrust rocket flow fields. The nominal engine thrust was 110 N. Tests were performed at chamber pressures of about 255 kPa, 370 kPa, and 500 kPa with oxidizer to fuel mixture ratios between 4.0 and 8.0. Two gaseous hydrogen/gaseous oxygen injector designs were tested with 60 percent and 75 percent fuel film cooling. The thruster and instrumentation designs were proven to be effective via hot fire testing. The thruster diagnostics provided inner wall temperature and static pressure measurements which were compared to the thruster global performance data. For several operating conditions, the performance data exhibited unexpected trends which were correlated with changes in the axial wall temperature distribution. Azimuthal temperature distributions were found to be a function of operating conditions and hardware configuration. The static pressure profiles showed that no severe pressure gradients were present in the rocket. The results indicated that small differences in injector design can result in dramatically different thruster performance and wall temperature behavior, but that these injector effects may be overshadowed by operating at a high fuel film cooling rate. HIGH EFFICIENCY DIRECT THERMAL TO ELECTRIC ENERGY CONVERSION FROM RADIOISOTOPE DECAY USING SELECTIVE EMITTERS AND SPECTRALLY TUNED SOLAR CELLS

Donald L. Chubb, Dennis J. Flood, and Roland A. Lowe (Cleveland State Univ., OH.) Aug. 1993 16 p Prepared for presentation at the Third European Space Power Conference, Graz, Austria, 23-27 Aug. 1993; sponsored by ESA and ASA
(RTOP 506-41-11)
(NASA-TM-106227; E-7945; NAS 1.15:106227) Avail: CASI HC A03/MF A01

Thermophotovoltaic (TPV) systems are attractive possibilities for direct thermal-to-electric energy conversion, but have typically required the use of black body radiators operating at high temperatures. Recent advances in both the understanding and performance of solid rare-earth oxide selective emitters make possible the use of TPV at temperatures as low as 1200K. Both selective emitter and filter system TPV systems are feasible. However, requirements on the filter system are severe in order to attain high efficiency. A thin-film of a rare-earth oxide is one method for producing an efficient, rugged selective emitter. An efficiency of 0.14 and power density of 9.2 W/KG at 1200K is calculated for a hypothetical thin-film neodymia (Nd_2O_3) selective emitter TPV system that uses radioisotope decay as the thermal energy source. DEVELOPMENT OF A HIGH SPECIFIC 1.5 TO 5 kW THERMAL ARCJET Interim Report No. 2, Nov. 1992 - Apr. 1993

M. Riehle, B. Glocker, M. Auweter-Kurtz, and H. Kurtz May 1993 21 p
(Grant NAGw-1736)
(NASA-CR-193133; NAS 1.26:193133; IRS-93-P7) Avail: CASI HC A03/MF A01

A research and development project on the experimental study of a 1.5-5 kW thermal arcjet thruster was started in 1992 at the IRS. Two radiation cooled thrusters were designed, constructed, and adapted to the test facilities, one at each end of the intended power range. These thrusters are currently subjected to an intensive test program with main emphasis on the exploration of thruster performance and thruster behavior at high specific enthalpy and thus high specific impulse. Propelled by simulated hydrazine and ammonia, the thruster's electrode configuration such as constrictor diameter and cathode gap was varied in order to investigate their influence and to optimize these parameters. In addition, test runs with pure hydrogen were performed for both thrusters. Author

EXPERIMENTAL AND THEORETICAL INVESTIGATIONS OF Cs-Ba VAPOR TACITRON INVERTER FOR POWER CONDITIONING IN SPACE POWER SYSTEMS
M. El-Genk, C. Murray, and B. Wernsman Jan. 1993 53 p
(Contract DE-FG02-92ER-75708)
(DE93-012971; DOE/ER-75708/T1; UNM-ISNPS-1-1993) Avail: CASI HC A04/MF A01

The operational characteristics of the Cs-Ba tacitron as a switch are investigated experimentally in three modes: (1) breakdown mode, (2) 1-5 mode, and (3) current modulation mode. The switching frequency, grid potentials for ignition and extinguishing of discharge, and the Cs pressure and emission conditions (Ba pressure and emitter temperature) for stable current modulation are determined. The experimental data is also used to determine the off-time required for successful ignition, and the effects of the aforementioned operational parameters on the ignition duty cycle threshold for stable modulation. The measured operational parameters include the following: switching frequency up to 20 kHz, hold-off voltage up to 180 V, current densities in excess of 15 A/sq cm, switch power density of 1 kW/sq cm, and a switching efficiency in excess of 90% at collector C. The voltage drop strongly depends on the Cs pressure and to a lesser extent on the emission conditions. Increasing the Cs pressure and/or the emission current lowers the voltage drop, however, for the same initial Cs pressure and emission conditions, the voltage drop in the 1-5 mode is usually lower than that during current modulation. As long as the discharge current is kept lower that the emission current, the voltage drop during stable current modulation could be as low as 3 V. DOE

The Twelfth Space Photovoltaic Research and Technology conference was held at the NASA Lewis Research Center from 20 to 22 Oct. 1992. The papers and workshops presented in this volume report substantial progress in a variety of areas in space photovoltaics. Topics covered include: high efficiency GaAs and InP solar cells, GaAs/Ge cells as commercial items, flexible amorphous and thin film solar cells (in the early stages of pilot production), high efficiency multiple bandgap cells, laser power converters, solar cell and array technology, heteroepitaxial cells, betavoltaic energy conversion, and space radiation effects in InP cells. Space flight data on a variety of cells were also presented. For individual titles, see N94-11381 through N94-11419.

A DETAILED STUDY OF THE PHOTO-INJECTION ANNEALING OF THERMALLY DIFFUSED InP SOLAR CELLS
R. J. Walters, G. P. Summers, and J. Bruening (Naval Postgraduate School, Monterey, CA.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 1-7 (For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

A detailed analysis of the annealing of thermally diffused InP solar cells fabricated by the Nippon Mining Co. is presented. The cells were irradiated with 1 MeV electrons, and the induced degradation is measured using deep level transient spectroscopy and low temperature (86 K) IV measurements. Clear recovery of the photovoltaic parameters is observed during low temperature (T is less than 300 K) solar illuminations (1 sun, AMO) with further recovery at higher temperatures (300 less than T less than 500 K). For example, the output of a cell which was irradiated up to a fluence of 1 x 10(exp 16) cm(sup -2) was observed to recover to within 5 percent of the pre-irradiation output. An apparent correlation between the recovery of I(sub sc) and the annealing of the H4 defect and of the minority carrier trapping centers is observed. An apparent correlation between the recovery of VO, and the annealing of the H5 defect is also observed. These apparent correlations are used to develop a possible model for the mechanism of the recovery of the solar cells. Author (revised)

HIGH TEMPERATURE ANNEALING OF MINORITY CARRIER TRAPS IN IRRADIATED MOCVD n(+)p InP SOLAR CELL JUNCTIONS
S. R. Messenger, R. J. Walters (Naval Research Lab., Washington, DC.), and G. P. Summers (Maryland Univ. Baltimore County, Catonsville.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 8-15
(For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

Deep level transient spectroscopy was used to monitor thermal annealing of trapping centers in electron irradiated n(+)p InP junctions grown by metalorganic chemical vapor deposition, at temperatures ranging from 500 up to 650K. Special emphasis is given to the behavior of the minority carrier (electron) traps EA (0.24 eV), EC (0.12 eV), and ED (0.31 eV) which have received considerably less attention than the majority carrier (hole) traps H3, H4, and H5, although this work does extend the annealing behavior of the hole traps to higher temperatures than previously reported. It is found that H5 begins to anneal above 500K and is completely removed by 630K. The electron traps begin to anneal above 540K and are reduced to about half intensity by 630K. Although they each have slightly different annealing temperatures, EA, EC, and ED are all removed by 650K. A new hole trap called H3'(0.33 eV) grows as the other traps anneal and is the only trap remaining at 650K. This annealing behavior is much different than that reported for diffused junctions. RADIATION EFFECTS IN HETEROEPITAXIAL InP SOLAR CELLS
I. Weinberg, H. B. Curtis, C. K. Swartz, D. J. Brinker, and C. Vargas-Aburto (Kent State Univ., OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 16-22
(For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

Heteroepitaxial InP solar cells, with GaAs substrates, were irradiated by 0.5 and 3 MeV protons and their performance, temperature dependency, and carrier removal rates determined as a function of fluence. The radiation resistance of the present cells was significantly greater than that of non-heteroepitaxial InP cells at both proton energies. A clear difference in the temperature dependency of V(sub oc), was observed between heteroepitaxial and homoepitaxial InP cells. The analytically predicted dependence of dV(sub oc)/dT on Voc was confirmed by the fluence dependence of these quantities. Carrier removal was observed to increase with decreasing proton energy. The results obtained for performance and temperature dependency were attributed to the high dislocation densities present in the heteroepitaxial cells while the energy dependence of carrier removal was attributed to the energy dependence of proton range. PROGRESS IN p(+)n InP SOLAR CELLS FABRICATED BY THERMAL DIFFUSION
D. J. Flood, D. J. Brinker, I. Weinberg, C. Vargas, Mircea Faur (Cleveland State Univ., OH.), Maria Faur (Cleveland State Univ., OH.), C. Goradia (Cleveland State Univ., OH.), M. Goradia (Cleveland State Univ., OH.), and N. S. Fatemi (Sverdrup Technology, Inc., Cleveland, OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 23-32 (For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

The performance results of our most recently thermally diffused InP solar cells using the p(+)n (Cd,S) structures are presented. We have succeeded in fabricating cells with measured AMO, 25 C V(sub oc) exceeding 880 mV (bare cells) which to the best of our knowledge is higher than previously reported V(sub oc) values for any InP homojunction solar cells.

The cells were fabricated by thinning the emitter, after Au-Zn front contacting, from its initial thickness of about 4.5 microns to about 0.6 microns. After thinning, the exposed surface of the emitter was passivated by a thin (approximately 50A) P-rich oxide. Based on the measured EQY and J(sub sc)-V(sub oc) characteristics of our experimental high V(sub oc) p(+)n InP solar cells, we project that reducing the emitter thickness to 0.3 microns, using an optimized AR coating, maintaining the surface hole concentration of 3 x 10(exp 18)cm(sup -3), reducing the grid shadowing from actual 10.55 percent to 6 percent and reducing the contact resistance will increase the actual measured 12.57 percent AMO 25 C efficiency to about 20.1 percent. By using our state-of-the-art p(+)n structures which have a surface hole concentration of 4 x 10(exp 18)cm(sup -3) and slightly improving the front surface passivation, an even higher practically achievable AMO, 25 C efficiency of 21.3 percent is projected. Author (revised)

ELECTROCHEMICAL CHARACTERIZATION OF p(+)n AND n(+)p DIFFUSED InP STRUCTURES **c76**

David M. Wilt, Maria Faur (Cleveland State Univ., OH.), Mircea Faur (Cleveland State Univ., OH.), M. Goradia (Cleveland State Univ., OH.), and Carlos Vargas-Aburto (Kent State Univ., OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 33-42 (For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

The relatively well documented and widely used electrolytes for characterization and processing of Si and GaAs-related materials and structures by electrochemical methods are of little or no use with InP because the electrolytes presently used either dissolve the surface preferentially at the defect areas or form residual oxides and introduce a large density of surface states. Using an electrolyte which was newly developed for anodic dissolution of InP, and was named the 'FAP' electrolyte, accurate characterization of InP related structures including nature and density of surface states, defect density, and net majority carrier concentration, all as functions of depth was performed. A step-by-step optimization of n(+)p and p(+)n InP structures made by thermal diffusion was done using the electrochemical techniques, and resulted in high performance homojunction InP structures. ACTIVATION ENERGY AND CAPTURE CROSS SECTION OF MAJORITY CARRIER TRAPS IN Zn DOPED InP **c76**

George Rybicki and Wendell Williams (Case Western Reserve Univ., Cleveland, OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 43-53 (For primary document see N94-11380 01-20)
Avail: CASI HC A03/MF A03

Schottky barrier diodes were fabricated on Zn doped InP Wafers. The diodes were radiation damaged with 2 MeV protons to a dose of 2 x 10(exp 12)cm(sup -2). The damage was analyzed by DLTS (deep level transient spectroscopy) using the double correlation technique. Capture cross sections were measured directly. Two major defects were observed in the DLTS spectra. The first defect, was H4 at Ev + 0.29 eV, with capture cross section 1.1 x 10(exp -17)cm(sup 2). The second defect, was H5 at Ev + 0.53 eV. Its capture cross section varied with temperature as described by the relationship sigma = sigma(sub 0) exp(delta(E)/kT) where sigma(sub 0) = 1.3 x 10(exp -19)cm(sup 2) and delta(E) = .08 eV. This relationship yields a sigma of 5.9 x 10(exp -21)cm(sup 2) at room temperature. The surprisingly small capture cross section of H5 and its temperature dependence are discussed in terms of the multiphonon emission process for carrier capture at the defect. The advantages of the improved experimental techniques used are also discussed. Author (revised)

EFFECTS OF SOLAR CELL ENVIRONMENT ON CONTACT INTEGRITY

Victor G. Weizer and Navid S. Fatemi (Sverdrup Technology, Inc., Cleveland, OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 54-63 (For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

The III-V semiconductors react extremely rapidly with most commonly used contact metallizations. This precludes the use of elevated temperatures in the contact formation process for solar cells and other shallow junction devices. These devices must rely upon contact metallizations that are sufficiently conductive in their 'as-fabricated' state. However, while there are a number of non-sintered metallizations that have acceptable characteristics, the lack of a sintering step makes them vulnerable to a variety of environmentally induced degradation processes. The degrading effects resulting from the exposure of unsintered devices to a humid environment and to a vacuum (space) environment are described. It is shown, further, that these effects are magnified by the presence of mechanical damage in the contact metallization. The means to avoid or prevent these degrading interactions are presented. MEASUREMENT OF THE MINORITY CARRIER DIFFUSION LENGTH AND EDGE SURFACE-RECOMBINATION VELOCITY IN InP **c76**

Sheila G. Bailey and Roshanak Hakimzadeh (Sverdrup Technology, Inc., Brook Park, OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 64-77 (For primary document see N94-11380 01-20)
Avail: CASI HC A03/MF A03

A scanning electron microscope (SEM) was used to measure the electron (minority carrier) diffusion length (L(sub n)) and the edge surface-recombination velocity (V(sub s)) in zinc-doped Czochralski-grown InP wafers. Electron-beam-induced current (EBIC) profiles were obtained in specimens containing a Schottky barrier perpendicular to the scanned (edge) surface. An independent technique was used to measure V(sub s), and these values were used in a theoretical expression for normalized EBIC. A fit of the experimental data with this expression enabled us to determine L(sub n). Author (revised)

SURFACE PASSIVATION OF InP SOLAR CELLS WITH InAlAs LAYERS **c76**

Raj K. Jain, Dennis J. Flood, and Geoffrey A. Landis (Sverdrup Technology, Inc., Brook Park, OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 78-87 (For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

The efficiency of indium phosphide solar cells is limited by high values of surface recombination. The effect of a lattice-matched In(0.52)Al(0.48)As window layer material for InP solar cells, using the numerical code PC-1D is investigated. It was found that the use of InAlAs layer significantly enhances the p(+)n cell efficiency, while no appreciable improvement is seen for n(+)p cells. The conduction band energy discontinuity at the heterojunction helps in improving the surface recombination. An optimally designed InP cell efficiency improves from 15.4 percent to 23 percent AMO for a 10 nm thick InAlAs layer. The efficiency improvement reduces with increase in InAlAs layer thickness, due to light absorption in the window layer. Author (revised)

(Contract NAS3-26244)
Avail: CASI HC A02/MF A03

Requirements for space power are increasingly emphasizing lower costs and higher specific powers. This results from new fiscal constraints, higher power requirements for larger applications, and the evolution toward longer distance missions such as a Lunar or Mars base. The polyimide based a-Si modules described are being developed to meet these needs. The modules consist of tandem a-Si solar cell material deposited directly on a roll of polyimide. A laser scribing/printing process subdivides the deposition into discrete cell strips which are series connected to produce the required voltage without cutting the polymer backing. The result is a large, monolithic, blanket type module approximately 30 cm wide and variable in length depending on demand. Current production modules have a specific power slightly over 500 W/Kg with room for significant improvement. Costs for the full blanket modules range from $30/Watt to $150/Watt depending on quantity and engineering requirements. Work to date focused on the modules themselves and adjusting them for the AMO spectrum. Work is needed yet to insure that the modules are suitable for the space environment. Author (revised)

INVESTIGATION OF THE RADIATION RESISTANCE OF TRIPLE-JUNCTION a-Si:H ALLOY SOLAR CELLS IRRADIATED WITH 1.00 MeV PROTONS

Kenneth R. Lord, II, Michael R. Walters, and James R. Woodyard *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 98-107 Sponsored in part by TRW (For primary document see N94-11380 01-20)
(Grant NAG3-833)
Avail: CASI HC A02/MF A03

The effect of 1.00 MeV proton irradiation on hydrogenated amorphous silicon alloy triple-junction solar cells is reported for the first time. The cells were designed for radiation resistance studies and included 0.35 cm(sup 2) active areas on 1.0 by 2.0 cm(sup 2) glass superstrates. Three cells were irradiated through the bottom contact at each of six fluences between 5.10E12 and 1.46E15 cm(sup -2). The effect of the irradiations was determined with light current-voltage measurements. Proton irradiation degraded the cell power densities from 8.0 to 98 percent for the fluences investigated. Annealing irradiated cells at 200 C for two hours restored the power densities to better than 90 percent. The cells exhibited radiation resistances which are superior to cells reported in the literature for fluences less than 1E14 cm(sup -2). Author (revised)

RESULTS OF SOME INITIAL SPACE QUALIFICATION TESTING ON TRIPLE JUNCTION a-Si AND CuInSe2 THIN FILM SOLAR CELLS

Robert L. Mueller and Bruce E. Anspaugh *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 108-117 Sponsored by USAF Phillips Lab. (For primary document see N94-11380 01-20)
Avail: CASI HC A02/MF A03

A series of environmental tests were completed on one type of triple junction a-Si and two types of CuInSe2 thin film solar cells. The environmental tests include electron irradiation at energies of 0.7, 1.0, and 2.0 MeV, proton irradiation at energies of 0.115, 0.24, 0.3, 0.5, 1.0, and 3.0 MeV, post-irradiation annealing at temperatures between 20 C and 60 C, long term exposure to air mass zero (AM0) photons, measurement of the cells as a function of temperature and illumination intensity, and contact pull strength tests. As expected, the cells are very resistant to electron and proton irradiation. However, when a selected cell type is exposed to low energy protons designed to penetrate to the junction region, there is evidence of more significant damage. A significant amount of recovery was observed after annealing in several of the cells. However, it is not permanent and durable, but merely a temporary restoration, later nullified with additional irradiation. Contact pull strengths measured on the triple junction a-Si cells averaged 667 grams, and pull strengths measured on the Boeing CuInSe2 cells averaged 880 grams. Significant degradation of all cell types was observed after exposure to a 580 hour photon degradation test, regardless of whether the cells had been unirradiated or irradiated (electrons or protons). Although one cell from one manufacturer lost approximately 60 percent of its power after the photon test, several other cells from this manufacturer did not degrade at all. Author (revised)

FLEXIBLE POLYCRYSTALLINE THIN-FILM PHOTOVOLTAICS FOR SPACE APPLICATIONS Abstract Only

J. H. Armstrong, B. R. Lanning, M. S. Misra, V. K. Kapur (International Solar Electric Technology, Inglewood, CA.), and B. M. Basol (International Solar Electric Technology, Inglewood, CA.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 118 (For primary document see N94-11380 01-20)
Avail: CASI HC A01/MF A03

Polycrystalline thin-film photovoltaics (PV), such as CIS and CdTe, have received considerable attention recently with respect to space power applications. Their combination of stability, efficiency, and economy from large-scale monolithic-integration of modules can have significant impact on cost and weight of PV arrays for spacecraft and planetary experiments. An added advantage, due to their minimal thickness (approximately 6 microns sans substrate), is the ability to manufacture lightweight, flexible devices (approximately 2000 W/kg) using large-volume manufacturing techniques. The photovoltaic effort at Martin Marietta and ISET is discussed, including large-area, large-volume thin-film deposition techniques such as electrodeposition and rotating cylindrical magnetron sputtering. Progress in the development of flexible polycrystalline thin-film PV is presented, including evaluation of flexible CIS cells. In addition, progress on flexible CdTe cells is presented. Finally, examples of lightweight, flexible arrays and their potential cost and weight impact is discussed. Author (revised)

InGaAs CONCENTRATOR CELLS FOR LASER POWER CONVERTERS AND TANDEM CELLS

S. Wojtczuk, S. Vernon, and E. Gagnon *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 119-128 (For primary document see N94-11380 01-20)
(Contracts NAS1-19258; NAS1-19592)
Avail: CASI HC A02/MF A03

In(0.53)Ga(0.47)As N-on-P concentrator cells were made as part of an effort to develop 1.315 micron laser power converters. The 1.315 micron laser power conversion efficiency was estimated as 29.4 percent (at 5.57 W/cm(sup 2)) based on an 86 percent measured external quantum efficiency at 1.315 microns, and a measured open circuit voltage (484 mV), and fill-factor (67 percent) at the equivalent AM0 short-circuit photocurrent (5.07 A/cm(sup 2)). A 13.5 percent percent AMO efficiency was achieved at 89 suns and 25 C. Measured one-sun and 100-sun AMO efficiency, log I-V analysis, and quantum efficiency are presented for InGaAs cells with and without InP windows to passivate the front surface. Windowed cells performed better at concentration than windowless cells. Lattice mismatch between InGaAs epilayers and InP substrate was less than 800 ppm. Theoretical efficiency is estimated for 1.315 microns laser power converters versus the bandgap energy. Adding aluminum to InGaAs to form In(x)Al(y)Ga(1-x-y)As is presented as a way to achieve an optimal bandgap for 1.315 microns laser power conversion. Author (revised)

THE EFFICIENCY OF PHOTOVOLTAIC CELLS EXPOSED TO PULSED LASER LIGHT

R. A. Lowe, G. A. Landis (Sverdrup Technology, Inc., Brook Park, OH.), and P. Jenkins (Sverdrup Technology, Inc., Brook Park, OH.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 129-146 (For primary document see N94-11380 01-20)
Avail: CASI HC A03/MF A03

Future space missions may use laser power beaming systems with a free electron laser (FEL) to transmit light to a photovoltaic array receiver. To investigate the efficiency of solar cells with pulsed laser light, several types of GaAs, Si, CuInSe2, and GaSb cells were tested with the simulated pulse format of the induction and radio frequency (RF) FEL. The induction pulse format was simulated with an 800-watt average power copper vapor laser and the RF format with a frequency-doubled mode-locked Nd:YAG laser. Averaged current vs bias voltage measurements for each cell were taken at various optical power levels and the efficiency measured at the maximum power point. Experimental results show that the conversion efficiency for the cells tested is highly dependent on cell minority carrier lifetime, the width and frequency of the pulses, load impedance, and the average incident power. Three main effects were found to decrease the efficiency of solar cells exposed to simulated FEL illumination: cell series resistance, LC 'ringing', and output inductance. Improvements in efficiency were achieved by modifying the frequency response of the cell to match the spectral energy content of the laser pulse with external passive components. Author (revised)

RESPONSE OF SILICON SOLAR CELL TO PULSED LASER ILLUMINATION

D. Willowby, D. Alexander, T. Edge, and K. Herren *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 147-154 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

The response of silicon solar cell(s) to pulsed laser illumination is discussed. The motivation was due to the interest of Earth to space/Moon power beaming applications. When this work began, it was not known if solar cells would respond to laser light with pulse lengths in the nanosecond range and a repetition frequency in the kHz range. This is because the laser pulse would be shorter than the minority carrier lifetime of silicon. A 20-nanosecond (ns) full width half max (FWHM) pulse from an aluminum-gallium/arsenide (Al-Ga-As) diode laser was used to illuminate silicon solar cells at a wavelength of 885 nanometers (nm). Using a high-speed digital oscilloscope, the response of the solar cells to individual pulses across various resistive loads was observed and recorded. Author (revised)

APPROACHES TO SOLAR CELL DESIGN FOR PULSED LASER POWER RECEIVERS

Raj K. Jain and Geoffrey A. Landis (Sverdrup Technology, Inc., Brook Park, OH.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 155-166 (For primary document see N94-11380 01-20)

(Contract NAS3-25266)

Avail: CASI HC A03/MF A03

Using a laser to beam power from Earth to a photovoltaic receiver in space could be a technology with applications to many space missions. Extremely high average-power lasers would be required in a wavelength range of 700-1000 nm. However, high-power lasers inherently operate in a pulsed format. Existing solar cells are not well designed to respond to pulsed incident power. To better understand cell response to pulsed illumination at high intensity, the PC-1D finite-element computer model was used to analyze the response of solar cells to continuous and pulsed laser illumination. Over 50 percent efficiency was calculated for both InP and GaAs cells under steady-state illumination near the optimum wavelength. The time-dependent response of a high-efficiency GaAs concentrator cell to a laser pulse was modeled, and the effect of laser intensity, wavelength, and bias point was studied. Three main effects decrease the efficiency of a solar cell under pulsed laser illumination: series resistance, L-C 'ringing' with the output circuit, and current limiting due to the output inductance. The problems can be solved either by changing the pulse shape or designing a solar cell to accept the pulsed input. Cell design possibilities discussed are a high-efficiency, light-trapping silicon cell, and a monolithic, low-inductance GaAs cell. Author (revised)

EOL PERFORMANCE COMPARISON OF GaAs/Ge AND Si BSF/R SOLAR ARRAYS

Thomas J. Woike *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 167-176 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

EOL power estimates for solar array designs are significantly influenced by the predicted degradation due to charged particle radiation. New radiation-induced power degradation data for GaAs/Ge solar arrays applicable to missions ranging from low earth orbit (LEO) to geosynchronous earth orbit (GEO) and compares these results to silicon BSF/R arrays. These results are based on recently published radiation damage coefficients for GaAs/Ge cells. The power density ratio (GaAs/Ge to Si BSF/R) was found to be as high as 1.83 for the proton-dominated worst-case altitude of 7408 km medium Earth orbit (MEO). Based on the EOL GaAs/Ge solar array power density results for MEO, missions which were previously considered infeasible may be reviewed based on these more favorable results. The additional life afforded by using GaAs/Ge cells is an important factor in system-level trade studies when selecting a solar cell technology for a mission and needs to be considered. The data presented supports this decision since the selected orbits have characteristics similar to most orbits of interest. Author (revised)

A HIGH SPECIFIC POWER SOLAR ARRAY FOR LOW TO MID-POWER SPACECRAFT

P. Alan Jones, Stephen F. White, T. Jeffery Harvey, and Brian S. Smith (Spectrolab, Inc., Sylmar, CA.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 177-187 (For primary document see N94-11380 01-20)

Avail: CASI HC A03/MF A03

UltraFlex is the generic term for a solar array system which delivers on-orbit power in the 400 to 6,000 watt per wing sizes with end-of-life specific power performance ranging to 150 watts-per-kilogram. Such performance is accomplished with off-the-shelf solar cells and state-of the-art materials and processes. Much of the recent work in photovoltaics is centered on advanced solar cell development. Successful as such work has been, no integrated solar array system has emerged which meets NASA's stated goals of 'increasing the end-of-life performance of space solar cells and arrays while minimizing their mass and cost.' This issue is addressed; namely, is there an array design that satisfies the usual requirements for space-rated hardware and that is inherently reliable, inexpensive, easily manufactured and simple, which can be used with both advanced cells currently in development and with inexpensive silicon cells? The answer is yes. The UltraFlex array described incorporates use of a blanket substrate which is thermally compatible with silicon and other materials typical of advanced multi-junction devices. The blanket materials are intrinsically insensitive to atomic oxygen degradation, are space rated, and are compatible with standard cell bonding processes. The deployment mechanism is simple and reliable and the structure is inherently stiff (high natural frequency). Mechanical vibration modes are also readily damped. The basic design is presented as well as supporting analysis and development tests. Author (revised)

TAB INTERCONNECTS FOR SPACE CONCENTRATOR SOLAR CELL ARRAYS

J. Avery, J. S. Bauman, P. Gallagher, and J. W. Yerkes *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 188-195 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

The Boeing Company has evaluated the use of Tape Automated Bonding (TAB) and Surface Mount Technology (SMT) for a highly reliable, low cost interconnect for concentrator solar cell arrays. TAB and SMT are currently used in the electronics industry for chip interconnects and printed circuit board assembly. TAB tape consists of sixty-four 3-mil/1-oz tin-plated copper leads on 8-mil centers. The leads are thermocompression gang bonded to GaAs concentrator solar cell with silver contacts. This bond, known as an Inner Lead Bond (ILB), allows for pretesting and sorting capability via nondestruct wire bond pull and flash testing. Destructive wire pull tests resulted in preferred mid-span failures. Improvements in fill factor were attributed to decreased contact resistance on TAB bonded cells. Preliminary thermal cycling and aging tests were shown excellent bond strength and metallurgical results. Auger scans of bond sites reveals an Ag-Cu-Tin composition. Improper bonds are identified through flash testing as a performance degradation. On going testing of cells are underway at Lewis Research Center. SMT techniques are utilized to excise and form TAB leads post ILB. The formed leads' shape isolates thermal mismatches between the cells and the flex circuit they are mounted on. TABed cells are picked and placed with a gantry x-y-z positioning system with pattern recognition. Adhesives are selected to avoid thermal expansion mismatch and promote thermal transfer to the flex circuit. TAB outer lead bonds are parallel gap welded (PGW) to the flex circuit to finish the concentrator solar cell subassembly. Author

SPACE STATION FREEDOM ADVANCED PHOTOVOLTAICS AND BATTERY TECHNOLOGY DEVELOPMENT PLANNING

Karen D. Brender, Spruce M. Cox (Boeing Defense and Space Group, Huntsville, AL.), Mark T. Gates (Boeing Defense and Space Group, Seattle, WA.), and Scott A. Verzwyvelt (Boeing Defense and Space Group, Seattle, WA.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 196-205 (For primary document see N94-11380 01-20) (Contract NAS1-19247)

Avail: CASI HC A02/MF A03

Space Station Freedom (SSF) usable electrical power is planned to be built up incrementally during assembly phase to a peak of 75 kW end-of-life (EOL) shortly after Permanently Manned Capability (PMC) is achieved in 1999. This power will be provided by planar silicon (Si) arrays and nickel-hydrogen (NiH2) batteries. The need for power is expected to grow from 75 kW to as much as 150 kW EOL during the evolutionary phase of SSF, with initial increases beginning as early as 2002. Providing this additional power with current technology may not be as cost effective as using advanced technology arrays and batteries expected to develop prior to this evolutionary phase. A six-month study sponsored by NASA Langley Research Center and conducted by Boeing Defense and Space Group was initiated in Aug. 1991. The purpose of the study was to prepare technology development plans for cost effective advanced photovoltaic (PV) and battery technologies with application to SSF growth, SSF upgrade after its arrays and batteries reach the end of their design lives, and other low Earth orbit (LEO) platforms. Study scope was limited to information available in the literature, informal industry contacts, and key representatives from NASA and Boeing involved in PV and battery research and development. Ten battery and 32 PV technologies were examined and their performance estimated for SSF application. Promising technologies were identified based on performance and development risk. Rough order of magnitude cost estimates were prepared for development, fabrication, launch, and operation. Roadmaps were generated describing key issues and development paths for maturing these technologies with focus on SSF application. Author (revised)

NEW EXPERIMENTAL TECHNIQUES FOR SOLAR CELLS

R. Lenk *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 217-225 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

Solar cell capacitance has special importance for an array controlled by shunting. Experimental measurements of solar cell capacitance in the past have shown disagreements of orders of magnitude. Correct measurement technique depends on maintaining the excitation voltage less than the thermal voltage. Two different experimental methods are shown to match theory well, and two effective capacitances are defined for quantifying the effect of the solar cell capacitance on the shunting system. Author

RADIATION EFFECTS IN Ga(0.47)In(0.53)As SOLAR CELLS c76

R. J. Walters, G. J. Shaw, G. P. Summers, and S. R. Messenger (SFA, Inc., Landover, MD.) *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 226-234 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

The effects of irradiating Ga(0.47)In(0.53)As p-i-n junctions with 1 MeV electrons were measured using Deep Level Transient Spectroscopy (DLTS) and both dark and illuminated (1 sun, air mass zero (AM0)) current-voltage (I-V) measurements. The I-V measurements were made over the range 100K less than T less than 350K. Temperature coefficients of the Ga(0.47)In(0.53)As photovoltaic parameters are presented which follow the same general behavior as other solar cell materials (e.g. Si and GaAs). Fits of the dark I-V data to the two term diode equation before irradiation were satisfactory, yielding an estimated band-gap energy of 0.79 eV. The recombination component of the dark current was found to increase linearly with fluence. DLTS detected two radiation-induced defect levels one shallow (E(sub c)-0.10 eV) and one near mid-gap (E(sub c)-0.29 eV), and it is the near mid-gap level which is expected to be the cause of the dark current increase. The radiation-induced degradation of the open circuit voltage is shown to be accurately predicted from the dark I-V measurements. The degradation of the open circuit voltage dominated the radiation response of the photovoltaic parameters while the short circuit current was only moderately degraded. This behavior is qualitatively explained in terms of the base thickness and dopant level. Appropriate changes in the device structure are suggested which should increase the radiation resistance. Isochronal thermal annealing induced recovery in the photovoltaic parameters at approximately 400K, coinciding with an annealing stage of the near mid-gap defect level. Author (revised)

INVESTIGATION OF ZnSe-COATED SILICON SUBSTRATES FOR GaAs SOLAR CELLS c76

Daniel A. Huber, Larry C. Olsen, Glen Dunham, and F. William Addis *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 235-248 Sponsored by USAF Phillips Lab. (For primary document see N94-11380 01-20)

Avail: CASI HC A03/MF A03

Studies are being carried out to determine the feasibility of using ZnSe as a buffer layer for GaAs solar cells grown on silicon. This study was motivated by reports in the literature indicating ZnSe films had been grown by metallorganic chemical vapor deposition (MOCVD) onto silicon with EPD values of 2 x 10(exp 5) cm(sup -2), even though the lattice mismatch between silicon and ZnSe is 4.16 percent. These results combined with the fact that ZnSe and GaAs are lattice matched to within 0.24 percent suggest that the prospects for growing high efficiency GaAs solar cells onto ZnSe-coated silicon are very good. Work to date has emphasized development of procedures for MOCVD growth of (100) ZnSe onto (100) silicon wafers, and subsequent growth of GaAs films on ZnSe/Si substrates. In order to grow high quality single crystal GaAs with a (100) orientation, which is desirable for solar cells, one must grow single crystal (100) ZnSe onto silicon substrates. A process for growth of (100) ZnSe was developed involving a two-step growth procedure at 450 C. Single crystal, (100) GaAs films were grown onto the (100) ZnSe/Si substrates at 610 C that are adherent and specular. Minority carrier diffusion lengths for the GaAs films grown on ZnSe/Si substrates were determined from photoresponse properties of Al/GaAs Schottky barriers. Diffusion lengths for n-type GaAs films are currently on the order of 0.3 microns compared to 2.0 microns for films grown simultaneously by homoepitaxy. Author (revised)

HETEROEPITAXIAL InP, AND ULTRATHIN, DIRECTLY GLASSED, GaAs 3-5 SOLAR CELLS c76

C. M. Hardingham and T. A. Cross *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 249-255 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

The commercial application of Indium Phosphide solar cells in practical space missions is crucially dependent upon achieving a major cost reduction which could be offered by heteroepitaxy on cheaper, more rugged substrates. Furthermore, significant mass reduction, compatibility with mechanically stacked multijunction cells, and elimination of the current loss through glue discoloration, is possible in III-V solar cells by the development of ultrathin, directly glassed cells. The progress of a UK collaborative program to develop high efficiency, homojunction InP solar cells, grown by MOCVD on Si substrates, is described. Results of homoepitaxial cells (is greater than 17 percent 1 Sun AM0) are presented, together with progress in achieving low dislocation density heteroepitaxy. Also, progress in a UK program to develop ultrathin directly-glassed GaAs cells is described. Ultrathin (5 micron) GaAs cells, with 1 Sun AM0 efficiencies up to 19.1 percent, are presented, together with progress in achieving a direct (adhesive-less) bond between the cell and coverglass. Consequential development to, for example, cell grids, are also discussed. Author (revised)

REVIEW OF BETAVOLTAIC ENERGY CONVERSION

Larry C. Olsen *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 256-267 (For primary document see N94-11380 01-20)

Avail: CASI HC A03/MF A03

Betavoltaic energy conversion refers to the generation of power by coupling a beta source to a semiconductor junction device. The theory of betavoltaic energy conversion and some past studies of the subject are briefly reviewed. Calculations of limiting efficiencies for semiconductor cells versus bandgap are presented along with specific studies for Pm-147 and Ni-63 fueled devices. The approach used for fabricating Pm-147 fueled batteries by the author in the early 1970's is reviewed. Finally, the potential performance of advanced betavoltaic power sources is considered. UV TESTING OF SOLAR CELLS: EFFECTS OF ANTIREFLECTIVE COATING, PRIOR IRRADIATION, AND UV SOURCE **c44**

A. Meulenberg *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 268-279 Sponsored in part by COMSAT Corporation (For primary document see N94-11380 01-20)

Avail: CASI HC A03/MF A03

Short-circuit current degradation of electron irradiated double-layer antireflective-coated cells after 3000 hours ultraviolet (UV) exposure exceeds 3 percent; extrapolation of the data to 10(exp 5) hours (11.4 yrs.) gives a degradation that exceeds 10 percent. Significant qualitative and quantitative differences in degradation were observed in cells with double- and single-layer antireflective coatings. The effects of UV-source age were observed and corrections were made to the data. An additional degradation mechanism was identified that occurs only in previously electron-irradiated solar cells since identical unirradiated cells degrade to only 6 +/- 3 percent when extrapolated 10(exp 5) hours of UV illumination. Author (revised)

THE UoSAT-5 SOLAR CELL EXPERIMENT: FIRST YEAR IN ORBIT **c44**

C. Goodbody *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 280-288 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

The results for the first year in orbit of the DRA solar cell experiment flying on the Surrey University UoSAT-5 satellite are described. Several problems were identified with the measured data, which are discussed along with the techniques used to remove or minimize the effect of the problems. After 1 year in orbit the majority of the cells flying on the experiment have undergone little or no degradation. The exception to this are all the ITO/InP cells, supplied by two different manufacturers, they are showing more degradation than the GaAs cells. This result is unexpected and currently unexplainable. It will be necessary to retrieve data from the experiment for several years to obtain the best results due to the relatively benign radiation environment. Author (revised)

RESULTS OF THERMAL VACUUM TESTS FOR THE PASP+ FLIGHT MODULES

Henry Curtis, Michael Piszczor, Don Guidice (Phillips Lab., Hanscom AFB, MA.), and Paul Severance (Phillips Lab., Hanscom AFB, MA.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 289-297 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

The PASP PLUS (Photovoltaic Array Space Power Plus Diagnostics) program is a photovoltaic experiment which will be flown on the Air Force satellite APEX (Advanced Photovoltaic And Electronic Experiment). APEX will be launched with a Pegasus during the summer of 1993. There are two other small experiments on APEX but PASP+ is the largest, uses the most power, and accounts for over 90 percent of the data requirements. The orbit is elliptical with apogee and perigee of 1050 and 190 nautical miles respectively. The inclination is 70 deg. The two main objectives of PASP+ are to determine the interactions between high voltage arrays and the space plasma environment and to determine the radiation damage characteristics of several newer types of solar cells. In order to determine the interactions with the space plasma, several of the individual cell strings will be biased to voltages up to plus or minus 500 V, and leakage currents and arcing rates will be measured. The radiation degradation characteristics will be determined by the continuous monitoring of I-V data for all of the cell strings. As part of an overall testing program, the PASP+ panels and controller were put through a thermal vacuum test in order to check the thermal analysis, obtain temperature coefficients for the individual modules, and have an end-to-end test of the entire PASP+ experiment. This thermal vacuum test is described briefly and the results obtained during that testing are discussed. Author (revised)

COMPUTATION OF PHOTOVOLTAIC PARAMETERS UNDER LUNAR TEMPERATURE VARIATION

Neelkanth G. Dhere and James V. Santiago *In* NASA. Lewis Research Center, Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 298-306 (For primary document see N94-11380 01-20)

Avail: CASI HC A02/MF A03

Photovoltaic (PV) arrays with regenerative-fuel-cell energy storage is a prime, power-system candidate for lunar photo-power. The PV module performance decreases at higher temperatures. Surface temperature variations of the moon are extreme, the maximum (noon) temperature being 384 K. The present work utilizes detailed computations of photovoltaic parameters with computer program developed earlier for the computation of optimum bandgaps of single- and two-junction solar cells at different temperatures, and calculates the power output of single and two-junction solar modules under different configurations which constitutes an improvement over the assumption of a linear variation of efficiency with temperature. The program also calculates the necessary PV-array size to satisfy stipulated levels of day- and night-time power consumption. Author

The Defense Research Agency (DRA) has been active in the photovoltaic field since the early 1960's, then as the Royal Aircraft Establishment (RAE). The early work was aimed at developing silicon cells, solar panels, and light-weight flexible arrays in support of the 'UK' and 'X' series of British scientific and technology satellites, for which the RAE was either the design authority or technical advisor. The X3 satellite - Prospero, launched in 1971 test flew 50 micron wrap-round silicon cells. The X4 satellite -

Miranda, launched in 1974 test flew a deployable flexible silicon array which was developed at the DRA. During this period an extensive range of test equipment was developed which was maintained, modernized, and extended to date. Following a period of reduced activity in the late 1970's and early 1980's the current program evolved. The programs that have been undertaken since 1983 are briefly summarized. These range from various cell developments, new types of coverglasses, flight experiments, radiation testing, primary cell calibration, and environmental testing. The current photovoltaic program is mainly funded by the UK Ministry of Defence and by the Department of Trade and Industry through the British National Space Center (BNSC). The program is aimed at research and development, both internally and with industry, to meet the customer's technical objectives and requirements and to provide them with technical advice. The facilities are also being used on contract work for various national and international organizations. Author (revised)

WORKSHOP ON HETEROEPITAXIAL InP SOLAR CELLS c76
I. Weinberg and R. W. Walters (Naval Research Lab., Washington, DC.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 326-328 (For primary document see N94-11380 01-20)
Avail: CASI HC A01/MF A03

In a generic sense, the justification for any sort of InP solar cell research applies, i.e. to take advantage of the inherently high radiation resistance and efficiency of InP solar cells. To be more specific, the approach is justified by its potential for significant cost reduction and the availability of greatly increased cell area afforded by substrates such as Si and Ge. The use of substrates, such as the latter two, would result in increased ruggedness, ease of handling, and improved manufacturability. The use of more rugged substrates would lead to a greatly increased capability for cell thinning leading to the desirable feature of reduced array weight. Author (revised)

WORKSHOP ON SOLAR ELECTRIC PROPULSION
David Bents and Dean Marvin (Aerospace Corp., El Segundo, CA.) *In its* Proceedings of the 12th Space Photovoltaic Research and Technology Conference (SPRAT 12) May 1993 p 331-333 (For primary document see N94-11380 01-20)
Avail: CASI HC A01/MF A03

A summary of the discussion at the workshop on solar electric propulsion (SEP) is presented. The purpose of ELITE SEP flight experiment is to demonstrate operation of solar array powered electric thrusters for raising spacecraft from parking orbit to higher altitudes, leading to definition of an operational SEP orbit transfer vehicles (OTV) for Air Force missions. Many of the problems or potential problems that may be associated with SEP are not well understood nor clearly identified, and system level phenomena such as interaction of thruster plume with the solar arrays cannot be simulated in a ground test. Therefore, an end-to-end system flight test is required to demonstrate solar electric propulsion. Derived from text

The workshop on new silicon cells held during SPRAT12 is summarized. A smaller than average group attended this workshop reflecting the reduction in research dollars available to this portion of the photovoltaics community. Despite the maturity of the silicon technology, a core of the group maintained an excitement about new developments and potential opportunities. The group addressed both the implications and the applications of recent developments. Topics discussed include: light trapping and ultrathin silicon cells; different uses for silicon cells; new silicon cell developments; and radiation tolerant high efficiency cells. Author (revised)

The Ultraviolet Plume Instrument (UVPI) is a small plume-tracking instrument flown on the Naval Research Laboratory's Low-power Atmospheric Compensation Experiment (LACE) satellite, which was launched on 14 February 1990. The UVPI's mission is to collect images of rocket plumes. Missile tracking in the ultraviolet range is advantageous because of extremely low Earth and solar background, extremely sensitive photodetectors that do not require cryogenic cooling, and very high optical resolution that is possible with optics of relatively modest size. The two cameras of the instrument use filters, image intensifiers, and charge-coupled device (CCD) detectors to observe sources in the ultraviolet, a tracker camera for target acquisition, a plume camera with a narrow field of view (0.184 deg by 0.137 deg), and four filters for data acquisition. Filters have passbands of 195 to 295 nm, 220 to 320 nm, 235 to 350 nm, and 300 to 320 nm. Rocket stages reaching 110-km altitude have been successfully detected and tracked by the UVPI from a range of 450 to 550 km for about 30 seconds. The spectral radiance and spectral radiant intensities of the plumes were extracted for the data by using a reference spectrum characteristic of micron-sized alumina particles at the melting-point temperature. AN OVERVIEW OF THE CAPABILITIES OF ARA FOR THE MEASUREMENT OF NOZZLE DISCHARGE AND THRUST
R. S. Sale, M. Elliott, and I. F. Burns Aug. 1992 12 p Presented at the European Forum on Wind Tunnels and Wind Tunnel Testing Techniques, Southampton, England, 14-17 Sep. 1992
(ARA-Memo-378) Avail: CASI HC A03/MF A01

Details are given of the present nozzle thrust and discharge measuring ability of Aircraft Research Association (ARA) and the practical application of the measurements explained. Two major facilities for the measurement of thrust and discharge, the Mach Simulation Tank (MST) and the Large Scale Thrust Measuring Rig (LSTMR) are described in detail. The history of the development of these facilities is discussed and present data quality standards illustrated. Special emphasis is placed on the need for high precision mass flow measurements. The use of reference nozzles for qualification tests is described and possible future evolution of both facilities presented. Author

HOT-GAS-SIDE HEAT TRANSFER CHARACTERISTICS OF SUBSCALE, PLUG-NOZZLE ROCKET CALORIMETER CHAMBER
Richard J. Quentmeyer (Sverdrup Technology, Inc., Brook Park, OH.) and Elizabeth A. Roncace Washington Jul. 1993 14 p
(RTOP 584-03-11)
(NASA-TP-3380; E-7614; NAS 1.60:3380) Avail: CASI HC A03/MF A01

An experimental investigation was conducted to determine the hot-gas-side heat transfer characteristics for a liquid-hydrogen-cooled, subscale, plug-nozzle rocket test apparatus. This apparatus has been used since 1975 to evaluate rocket engine advanced cooling concepts and fabrication techniques, to screen candidate combustion chamber liner materials, and to provide data for model development. In order to obtain the data, a water-cooled calorimeter chamber having the same geometric configuration as the plug-nozzle test apparatus was tested. It also used the same two showerhead injector types that were used on the test apparatus: one having a Rigimesh faceplate and the other having a platelet faceplate. The tests were conducted using liquid oxygen and gaseous hydrogen as the propellants over a mixture ratio range of 5.8 to 6.3 at a nominal chamber pressure of 4.14 MPa abs (600 psia). The two injectors showed similar performance characteristics with the Rigimesh faceplate having a slightly higher average characteristic-exhaust-velocity efficiency of 96 percent versus 94.4 percent for the platelet faceplate. The throat heat flux was 54 MW/m(sup 2) (33 Btu/in.(sup 2)-sec) at the nominal operating condition, which was a chamber pressure of 4.14 MPa abs (600 psia), a hot-gas-side wall temperature of 730 K (1314 R), and a mixture ratio of 6.0. The chamber throat region correlation coefficient C(sub g) for a Nusselt number correlation of the form Nu =C(sub g)Re(sup 0.8)Pr(sup 0.3) averaged 0.023 for the Rigimesh faceplate and 0.026 for the platelet faceplate. TRIBOLOGICAL CHARACTERISTICS OF SPUTTERED Au/Cr FILMS ON ALUMINA SUBSTRATES AT ELEVATED TEMPERATURES Final Report
P. A. Benoy and C. DellaCorte May 1993 15 p Presented at the International Conference on Metallurgical Coatings and Thin Films, San Diego, CA, 17-21 Apr. 1993; sponsored by the American Vacuum Society
(Contract DE-AI01-91CE-50306; RTOP 505-63-1A)
(NASA-TM-106078; DOE/NASA/50306-3; E-7692; NAS 1.15:106078)
Avail: CASI HC A03/MF A01

Research to evaluate the tribological properties of alumina pins sliding against thin sputtered gold films deposited on alumina disk substrates is described. A 250 A thick chromium interlayer was first deposited onto the alumina test disks to enhance adhesion and high temperature wetting of the gold films. The Au/Cr films were tribotested in pure sliding in a pin-on-disk tribometer under a 4.9 N load at 1m/s. The test atmosphere was room air at temperatures of 25, 500, and 800 C and the test duration varied from 60 to 540 min. The use of the Au/Cr films reduced friction by about a factor of two compared to the unlubricated alumina sliding couple. The coatings prevented wear of the alumina substrate disks and reduced pin wear by one to two orders of magnitude. In addition, wear lives in excess of 200,000 sliding passes (9 hr) were observed during sliding at 800 C. The results suggest that these films show promise for the practical lubrication of many high temperature sliding components. Author (revised)

STUDIES IN BIOORGANIC CHEMISTRY Final Report
Jeffrey D. Winkler 2 Jun. 1993 3 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1886)
(AD-A265532) Avail: CASI HC A01

The grant addressed two issues of fundamental importance in biomimetic chemistry that had not been successfully imitated in a non-enzymatic system at the time at which this project started: the conformational flexibility of the enzyme active site and the consequences of such mobility for catalysis, and the stereoselective formation of carbon-carbon bonds using compounds that are based on the ubiquitous biological methylating agent S-adenosylmethionine. The photodynamic macrocycles that were originally proposed are not only fascinating molecules because of their unique structural effects, but were designed to be useful in the active transport of both metals and organic molecules which would have obvious implications in processes like the extraction of metals and organic molecules from aqueous solutions. The mimics of S-adenosylmethionine that were proposed in the original contract were to be applied to a variety of alkylation reactions and could ultimately be applied to the development of site-specific reagents for DNA functionalization, thereby providing an important control mechanism for gene expression. PROCESS MODELLING FOR MATERIALS PREPARATION EXPERIMENTS Semiannual Progress Report No. 8, 1 Feb. - 31 Jul. 1993
Franz Rosenberger and J. Iwan D. Alexander 1993 30 p
(Grant NAG8-790)
(NASA-CR-193556; NAS 1.26:193556) Avail: CASI HC A03/MF A01

The main goals of the research consist of the development of mathematical tools and measurement of transport properties necessary for high fidelity modeling of crystal growth from the melt and solution, in particular for the Bridgman-Stockbarger growth of mercury cadmium telluride (MCT) and the solution growth of triglycine sulphate (TGS). Of the tasks described in detail in the original proposal, two remain to be worked on: development of a spectral code for moving boundary problems, and diffusivity measurements on concentrated and supersaturated TGS solutions. During this eighth half-year period, good progress was made on these tasks. Author (revised)

ADVANCED MATERIALS FOR LIGHTWEIGHT STRUCTURES
W. R. Burke, comp. Oct. 1992 405 p In ENGLISH and FRENCH Symposium held in Noordwijk, Netherlands, 25-27 Mar. 1992; sponsored by Commission of the European Communities and EUREKA
(ESA-SP-336; ISBN-92-9092-186-2; ETN-93-93943) Copyright Avail: CASI HC A18/MF A04

Papers covering a wide range of emerging materials and applications, presented at a symposium which recognized the importance of interdisciplinary interests in any structural materials development, are presented. The consolidation of work in reinforced plastics, which has seen widespread use for satellite payloads and structures, together with use in launch vehicle construction, is reflected. A strong interest in thermoplastics is evident. There is also a clear realization that further exploitation of isotropic metals is achievable; the development of aluminum/lithium alloys is used as a typical example. Aspects related to the need for materials resistant to high temperature and whose structural integrity can be assured, and to the need for materials which can perform effectively at cryogenic temperatures, are reflected. For individual titles, see N94-10002 through N94-10069.

LIGHTWEIGHT CFRP FRAME STRUCTURES FOR A ROTEX-DERIVED MANIPULATOR SYSTEM
Hermann Hald *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 21-27 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

A lightweight manipulator system is under development which is derived from the German Robotic Technology Experiment (Rotex). It is realized by combining ultralight CFRP (Carbon Fiber Reinforced Plastic) frame structures, which are fabricated by filament winding on a lost core, and powerful joint driving units of a new design concept. The overall modular system concept is discussed, and the chosen frame structure design and its geometry, load introduction, joint integration and fabrication method, are described. Results of a successful static loading test under a combined torsion/bending worst case loading are compared with load assumptions and calculated strain and deflection distributions evaluated by a detailed finite element analysis. Calculated results on the influence of material anisotropy combined with slightly curved truss beam elements due to the fabrication method are discussed as well as sensitivity due to local impact. ESA

DESIGN AND DEVELOPMENT OF A CFRP CENTRAL CYLINDER FOR SATELLITES
A. Jimenez, V. Diaz, F. Cespedosa, and W. J. Rits (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, Advanced Materials for Lightweight

Structures Oct. 1992 p 33-38 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

The central cylinder of a satellite is the element of the structure that transmits all the loads acting on the structure subsystem to the launcher interface and with its stiffness influences the natural frequencies of the satellite. The high performance demanded of spacecraft structures makes it necessary to use materials with a high stiffness/mass ratio in order to obtain the lightest structure, since the mass is one of the most important parameters in space structures. For this reason, it is almost mandatory to use carbon fiber technology for these structures. The development of a central cylinder with the main objective of establishing appropriate and cost effective design and manufacturing techniques is described. ESA

AN APPROACH TO HIGH PRECISION ANTENNA STRUCTURES BY A CFRP CORE SANDWICH CONCEPT
A. Alonso, A. Cuadrado, A. Bonet, and H. Stark (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 39-44 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

High precision antenna structures such as the one foreseen for the FIRST (Far Infrared and Submillimeter Telescope) project require very high manufacturing accuracy, ultrahigh assembling precision, and obviously, very stable materials. A sandwich concept is thought to be one of the feasible options for the manufacturing of the FIRST project antenna, provided that the core has a low coefficient of thermal expansion. The development of an adequate core is thereby needed. A study was carried out in which a low cost and reliable CFRP (Carbon Fiber Reinforced Plastic) core was designed, analyzed, manufactured, and tested for mechanical and thermomechanical behavior. A double curvature sandwich panel having a CFRP core was manufactured as a feasibility concept model, and its thermal stability is being measured. ESA

LOW COST AND THERMALLY STABLE SANDWICH DESIGN FOR FIRST
G. Helwig, R. Sippel, and H. Stark (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 45-49 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

The technical approach for the small version of the FIRST (Far Infrared and Submillimeter Space Telescope) antenna system is guided by the idea of showing the feasibility of a simple and consequently lower cost design which can meet the stringent requirement for proper operation of 7 microns of overall RSS deformation. The concept is a 'panel only' design which needs no additional supporting framework for the reflector surface. The reflector is an all CFRP (Carbon Fiber Reinforced Plastic) sandwich construction having such a low coefficient of thermal expansion that deformations under even large temperature changes are very small. Manufacturing accuracy has to be very precise. Different specimens and a reflector with the size of 500 by 500 mm were built and thermally tested (coefficient of thermal expansion measurements). Measured deformations were compared with analysis results. ESA

Carbon/Carbon (C/C) and Carbon/Silicon Carbide (C/SiC) panels were manufactured for a reusable load carrying heat shield. Investigations of design concepts led to the application of cost efficient manufacturing and assembling methods. Via C/C and niobium screws, the individual panels are easily joinable to complex structures. Thermomechanical analysis and high temperature tests of joining elements confirmed the feasibility of two different design concepts: the double wall version and the resin transfer molding stringer stiffened concept. The hybrid materials developed are named fiber metal laminates (ARALL). These materials are built up from thin metal alloy sheets that alternate with unidirectional or cross ply prepregs. Various fibers are applied in this concept, such as aramid, R glass, and carbon fiber materials. These fibers offer outstanding mechanical and fatigue properties as well as fracture toughness. Fiber metal laminates with titanium (alloy) sheets are primarily developed for space applications. Structural applications up to 250 C are possible while preserving good mechanical and fatigue strength. The mechanical properties of fiber metal laminates, in general, and laminates with titanium alloy sheets and carbon fibers, in particular, are discussed and compared with other materials. Epoxy and thermoplastic (PEEK) adhesives were tested. Limitations on formability in manufacturing processes are discussed. An example of a space application of GLARE in the Hermes space suit is shown regarding production and forming techniques. ESA

The considerable interest in the application of refractory anisotropic materials to the design of shell components, which are used in the very hot regions of future hypersonic flight and reusable reentry vehicle structures, is discussed. These materials are often homogeneous in the macroscopic scale but anisotropic. Typical examples are pyrolytic graphite (obtained by vapor deposition) and more recently, carbon fiber reinforced carbon (C/C) and carbon fiber reinforced silicon carbide (C/SiC). The carbon fiber reinforcement of C/C and C/SiC often consists of layers of fabrics (0/90 deg), resulting in a behavior that is nearly isotropic in the plane of the shell but differs in the perpendicular (thickness) direction. The study focuses on such transversely isotropic materials and deals with distortions and residual stresses in shells made of such materials and resulting from uniform temperature changes. ESA

The analysis of angle ply carbon/epoxy laminated composites when subjected to uniaxial and biaxial stresses is presented. Three classes of interwoven pattern filament wound cylindrical specimens are studied in order to compare the influence of angle on the mechanical behavior of the laminate. Three dimensional finite element and thin shell analyses were first applied to the problem in order to predict global elastic behavior of specimens subjected to uniaxial loads. Different failure criteria were then adopted to investigate specimens' failure and experimental tests were carried out for a comparison with numerical results. Biaxial stress conditions were produced by applying combinations of internal pressure and axial tensile and compressive loads to the specimens. ESA

Within the Ariane 5 booster case development, combined pressure and axial load tests were carried out on tubes of the booster material 48 CrMoNiV 4 10 to determine the yield and burst criteria under biaxial loading conditions. The tests showed a burst type failure. At the intermediate stress ratios of 1:2 and 2:1 the results fall in between the von Mises and Tresca criteria. Based on this examination, the J2 based von Mises criterion can be a good first approximation of the biaxial behavior when prediction of yielding is required. In the calculation of the fracture, the (J2, J3) based Drucker theory is more appropriate. Based on the unified approach in this work, all named criteria can be simulated using simple generalized relationship. The coefficient necessary for the application are fitted based on the experimental results. ESA

DESIGN WITH HIGH STRENGTH STEEL: A CASE OF FAILURE AND ITS IMPLICATIONS **c39**
Klaus Rahka *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 93-99 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

A recent proof test failure of a high strength steel pressure vessel is scrutinized. Apparent deficiencies in the procedures to account for elasto-plastic local strain are indicated for the applicable routine (code) strength calculations. Tentative guidance is given for the use of material tensile fracture strain and its strain state (plane strain) correction in fracture margin estimation. A hypothesis that the calculated local strain is comparable with a gauge length weighted tensile ductility for fracture to initiate at a notch root is given. A discussion about the actual implications of the failure case and the suggested remedy in the light of the ASME Boiler and Pressure Vessel Code section 3 and 8 is presented. Further needs for research and development are delineated. Possible yield and ductility related design limits and their use as material quality indices are discussed. ESA

The evaluation of acoustic fatigue problems on aerospace structural elements is considered through finite element modeling of their dynamic behavior. A computer code was developed for this purpose. In order to validate the approach, RMS (Root Mean Square) computed stresses were compared with corresponding tests recorded on different structural components. S-N curves were established from representative coupon tests of typical panel junctions and stiffener sections at different levels of RMS deformation. These results were used to determine an estimated fatigue life for the full size component, to be correlated by fullscale test. ESA

An UltraSonic Gas Atomization (USGA) unit was built. Based on experiences in planar flow casting (PFC), melt dpinning (MS), and first test runs with USGA, the chamber construction and melting unit were strongly modified and a PC based control and data collection system was built up. In the final test runs Al-8Fe, Al-12Fe, and Al-12Fe-2V-2.5Si alloys were gas atomized in patches of 1 kg. Ribbons produced by PFC technique and chopped into flakes were used as reference materials. Microstructure of powders was finer and more homogeneous than that of flakes. Powders and flakes were extruded into rods, and their mechanical and hardness values were tested at different temperatures. ESA

The iron-rich iron aluminides are highly oxidation and sulfidation resistant and display good mechanical stength combined with low density. Two alloys, prepared by vacuum casting, were worked by compression in order to study the recrystallization conditions. After high temperature compression tests, two types of microstructure were observed: an equiaxed structure and a bimodal structure. Toughness tests were carried out on the compressed materials at 20 C. For the homogeneous structures with coarse grains, the energy values are lower than 37 J/sq cm; for the bimodal structures, these values are higher than 50 J/sq cm. Two deformation temperatures were studied in tensile tests: 950 and 1100 C. The strain rate was shown to be the critical parameter which controls the ductility of FeAl at a defined temperature. ESA

A tradeoff study demonstrated that up to 17 percent weight savings could be obtained on a selected ring component. The study indicated that in order to benefit fully from the advantages of Al-Li alloys, components for redesign must have a stiffness critical element. In order to determine the mechanical suitability, a test program was performed on an Al-Li forging. Tensile, compression, fracture toughness, and fatigue crack growth behavior was evaluated. In general, all properties are promising, though fracture toughness and fatigue crack growth in the ST orientation are relatively poor. In conclusion, the project findings have been promising, and application of Al-Li on satellites and other spacecraft structures must now be seriously considered. ESA

MECHANICAL AND FATIGUE PROPERTIES OF FIBRE REINFORCED ALUMINIUM-LITHIUM ALLOY AND ALUMINIUM-LITHIUM MMC BASED LAMINATES **c26**

E. P. Hunt, P. J. Gregson, R. Moreton (Defence Research Agency, Farnborough, England.), and C. J. Peel (Defence Research Agency, Farnborough, England.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 125-128 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

Continuous fiber reinforced laminates offer excellent resistance to fatigue crack growth and are potentially attractive for thin sheet damage tolerant aerospace applications. The current work set out to investigate the mechanical and fatigue properties of Al-Li alloy and Al-Li MMC (Metal Matrix Composites) laminates reinforced by carbon, aramid, and glass fibers. The low density of the lithium containing alloy and MMC causes the laminates to exhibit excellent specific strength and stiffness. For the fiber reinforcement to be beneficial to fatigue strength, the stiffness of the fibers must exceed that of the metallic components; in the present laminates, carbon fibers are shown to be advantageous. Fatigue crack growth rates are low and decrease with increasing fiber stiffness and increasing R ratio (increasing crack length). These effects are attributed to the influence of fiber bridging of the fatigue crack. ESA

UNIVERSAL ADJUSTABLE MOULD FOR ANTENNA REFLECTORS **c31**
Ulrich Trabandt and Rafael GarciaPrieto (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 155-160 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

The investigation of a concept to produce solid reflectors with different shapes for space application with very good surface accuracy is reported. The adjustable mold should be used for curing composite materials by autoclave treatment under heat and pressure. The result of the concept selection investigation was the bed of nails concept together with a thermoplast mold skin. Backed by creep behavior tests of the thermoplast and trials on the model mold, the appropriate parameters were found to form the thermoplast mold skin over the contour-giving nailheads. Once formed at a temperature of around 200C, the mold skin remains stable during the reflector curing process. The requirement for the contour accuracy can be fully met. The root mean square values of the formed thermoplast mold skin were between 20 and 40 micrometers and for the elegant breadboard reflector panel less than 44 micrometers. ESA

WELDABILITY OF MARAGING STEELS **c26**
Ryban Dusan *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 161-164 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

Metallurgical weldability of martensitic hardenable steels and the applicable welding technologies are addressed. The martensitic hardenable steels are the alloys of iron and nickel designed in such a way to provide high strength and high fracture toughness simultaneously. These properties are attained by hardening of the low carbon martensite, which is formed on the austenitization temperatures. Martensite is formed regardless of the cooling rate and is relatively soft, but by ageing at 480C it hardens due to precipitation of intermetallic phases. The welded joints show three characteristic heat affected zones, whereas the central narrowest one (heated approximately at 600 to 730C) is the weakest point of the weld. The most suitable technologies seem to be welding in shielding gases, friction welding, plasma arc and electron beam welding. ESA

DEFORMATION MECHANISMS OF CONTINUOUS FIBRE-REINFORCED THERMOPLASTIC COMPOSITES DURING MANUFACTURING: A PROBABILISTIC APPROACH
Dimitri A. Bofilios and C. A. M. vandenEnde (Keuring van Electrotechnische Materialen N.V., Arnhem, Netherlands.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 173-177 (For primary document see N94-10001 01-24)
(Contract BE-3062-89/BREU-268)
Copyright Avail: CASI HC A01/MF A04

The flow mechanism that takes place during consolidation, under constant load, of a unidirectional thermoplastic composite laminate, is modeled. The application of normal force results in a pressure gradient within the material, thus inducing transverse flow. In a deformation process, the fibers constrain the flow of the resin but are themselves convected with the resin. It was observed that during consolidation, a resin rich layer is formed between successive plies. The thickness of each of these resin layers is defined by the variability and non uniformity of the consolidation process. The analysis uses the concept of an incompressible viscous Newtonian fluid to describe the behavior of the resin layers while plies are modeled according to the theory of highly anisotropic imcompressible viscous fluids. ESA

(Contract BE-3062-89/BREU-268)
Copyright Avail: CASI HC A01/MF A04

Analytical models describing the preheating and the unsteady state conduction phenomena during the initial stages of manufacturing are presented. To expedite the process, the semi-product is preheated dielectrically (microwave heating), followed by stamping at a temperature below the T(sub g) of the matrix. The model developed to describe the microwave heating process is based on the notion of the Poynting vector which represents the energy flow per unit area in an electromagnetic wave. The analytical model used for predicting the temperature profiles in the specimen during stamping is based on transient heat conduction principles. In order to analyze the effects of process variability, simulation models were developed. These models allow for probabilistic inputs of either the processing variables or geometrical/material parameters. ESA

COST EFFECTIVENESS OF STRUCTURAL APPLICATIONS OF FIBRE REINFORCED THERMOPLASTICS **c27**
Winfried Werner *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 185-190 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

In the past years, graphite fiber reinforced thermoplastics were investigated for their possible application in structural components on aircrafts. Initially, cost savings were expected from the known advantages of these materials compared to graphite fiber reinforced epoxy resins. Since thermoplastics, as opposed to thermosets, do not cure but solidify during the cooling process of the melt, very short manufacturing cycles can be achieved. On account of the saving potential of fiber reinforced thermoplastics studies were carried out to investigate and evaluate several manufacturing concepts. ESA

APPLICATION OF ADVANCED THERMOPLASTICS **c27**
Arnt R. Offringa *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 191-195 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

Continuous fiber reinforced thermoplastic composites are maturing and moving into series production. The main driver for the application of thermoplastics is reduced part cost. Products can be produced cost effectively by applying certain innovative manufacturing processes. A number of these have been developed, among others: thermofolding, pressforming, hot dimpling and welding. The amount of processes is expanding rapidly. Development is often carried out jointly with partners, for example with material suppliers. In this manner, development efforts are speeded up, each party bringing in its own expertise. Government supported cooperation programs offer an extra incentive for industrial teamwork. Examples of products which are in series production are aircraft ice protection plates and wing panels as well as medical patient support panels. Applications outside the aerospace market are high end niche products such as medical support tables and robot arms. Thermoplastics are a young growth market with plenty of potential. ESA

TAPE WINDING OF THERMOPLASTIC COMPOSITES **c27**
K. Lahteenkorva, P. Peltonen, P. Jarvela, and P. Tormala *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 203-206 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

The effects of process parameters in thermoplastic tape winding are addressed. Analysis of processing parameters included: mandrell temperature, prepreg tension, roller compression on in situ consolidation, prepreg and wound surface warming, and winding speed. The effect of processing parameters on the wound part was evaluated by several different mechanical tests. Axial strength was the best indicator of wound part quality. Mandrell temperature and consolidation pressure effected mechanical properties most. In addition, suitability of the Taguchi method for this kind of application was studied. Results suggest the method is useful in limited circumstance for thermoplastic composite winding. ESA

SPECIAL PROBLEMS OF 3-D ULTRASONIC QNDI TECHNIQUES AND APPLICATIONS TO COMPOSITES AEROSPACE STRUCTURES c38

G. Sala, M. Anghileri, and A. Antoniazzi (Centro Sviluppo Applicazioni, Milan, Italy.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 209-215 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

A theoretical and experimental research activity carried out in order to set up a three dimensional (3D) ultrasonic QNDI (Quantitative Non Destructive Inspection) technique able to assess damage state of composite laminates is summarized. The role played by surface roughness, laminate thickness, fiber orientation, damage location and defect superposition were investigated. Signal acquisition and optimization processes were considered: ultrasonic spectroscopy has proven to be a suitable technique, consisting in the study of ultrasonic waveforms resolved into their Fourier frequency components; quantitative information can be extracted from the spectrum of the received ultrasonic signal and time of flight of ultrasounds. Various signal processing techniques were evaluated, relevant to complete waveform analysis: digital and analog filtering procedures, sampling, smoothing, fast Fourier transform, convolution and deconvolution. DESIGN OF INSPECTION AND ACCEPTANCE TEST METHODOLOGY FOR TIG WELDED ALUMINUM-ALLOY BRACKET FOR CAMERA HOUSINGS FOR IRS-1A SPACE CRAFT AND EXECUTING IT c38

V. K. Manglik, Rajeev Vaghmare, and A. K. Shah *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 217-221 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

The Indian Remote Sensing Satellite (IRS) 1A was the first indigenously developed operational remote sensing satellite. The most critical element in the satellite was the remote sensing camera. The camera was mounted on aluminum alloy bracket which was fabricated by TIG welding. The methodology of acceptance and inspection of the TIG welded bracket is presented and discussed. These efforts not only provided the confidence in reliable welded joint but also provided trouble free operation of the camera on board the satellite for its whole life. ESA

In research, processing and application of composite materials, a strong demand for nondestructive characterization has developed. For several years it has continuously been stated in material science conferences that the performance of nondestructive techniques is dissatisfying in the case of composites. In attempting to bridge this technological gap, methods of nondestructive characterization of composites by X-ray scanning topography were created. They are capable of imaging microstructural properties by crystallographic contrast, interface sensitivity and orientational selectivity. ESA

APPLICATION OF THE INFRARED PHOTOACOUSTIC SPECTROSCOPY TO THE STUDY OF THE CURE MECHANISMS OF STRUCTURAL EPOXY ADHESIVES c25

J. L. Coppee *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 233-238 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

An interesting application of photoacoustic detection is the study of curing process of epoxy resins. Using this technique combined with thermal analysis method, differential scanning calorimetry and dynamic mechanical spectroscopy, the polymerization of two structural adhesives, designated A and B was studied. Fourier transform infrared spectroscopy photoacoustics was the only way to investigate the cure of the adhesive films with their carrier. In the adhesive A, the dicyandiamide, one of the curing agents, participates in reactions at the end of the cure, when the consumption of the epoxide groups stops. Those reactions, which are not exothermic, seem to increase the glass transition temperature and to homogenize the network. The cure mechanisms of the adhesive B consists of consecutive reactions: at the beginning of the cure, the exothermic reactions occur without consumption of epoxide groups and with a weak increase of T(sub G), in a second step, the epoxide groups participate in etherification reactions. AN ULTRALIGHT CARBON-CARBON COMPOSITE WITH AMORPHOUS MATRIX

Pentti O. Kettunen, Quancheng Gu, and Toivo K. Lepisto *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 245-248 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

The methods of controlled porosity are applied to pyrolization of carbon fiber reinforced phenolic thermosets in order to avoid the cracking of the matrix during pyrolization and to get the formed matrix into amorphous state. As based on results of optical microscopy, X-ray and selected area electron diffraction, TEM, and HREM, the goals are reached successfully. As compared to pure amorphous carbon, the carbon fiber reinforced modification has at room temperature bending strength values about four times higher, and exhibits quasi ductile fracture behavior. At 1500C, the composite reaches bending strength values from 550 N/sq mm to about 1000 N/sq mm. As the density of the structure is 1.25 to 1.35 g/cu cm, the specific bending strengths of the structure is less than or equal to 800,000 Nmm/g. ESA

NEW PROCESSES FOR LIGHTWEIGHT CERAMIC MATRIX COMPOSITES c27

A. Muehlratzer, K. Handrick, H. Koeberle, and K. Peetz *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 249-254 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

The current status of the industrial development of a thermal and pressure gradient CVI (Chemical Vapor Infiltration) process for the manufacture of CMC (Ceramic Matrix Composites) parts with SiC matrix is described. The short periods of time required for CVI densification with this process (in the order of several ten hours) makes the process cost effective and allows for short development cycles. Tensile strengths of up to 320 MPa for C/SiC and over 200 MPa for SiC/SiC together with strain tolerance were obtained. Within the German Hypersonics Technology Program the process is applied for the development of a CMC demonstrator part. A sol-gel derived alumina CMC is used for a newly developed insulation in the thermal protection system of the European Spaceplane Hermes. Thin alumina fiber reinforced alumina foils obtained by sol impregnation of fiber fleeces and coated with noble metal thin films are applied as reflective screens. ESA

SPIN-ROLLING, WELDING, AND HEAT TREATMENT OF ALUMINIUM 2219 FOR ARIANE 5 GAM HIGH PRESSURE VESSEL LINERS c31
W. Radtke *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 263-266 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A01/MF A04

Cylindrical liners made of Al 2219 may be spinrolled if both recrystallization and metastable precipitates can be avoided during forging or preparatory heat treatment. So welding is to be limited to circumferential joints. Pore-free welds are attainable immediately after hydroxide layer removal by diamond cutting without grease application. The EB vacuum is favorable to porosity suppression. A complete heat treatment of the liner incorporating solutionizing, water quenching and ageing leads to 100 percent weld efficiency. Pressure stabilization avoids buckling. Subsequent carbon fiber winding, curing and plastic prestressing of the liner results in an efficient high pressure vessel for hydrogen service. ESA

Copyright Avail: CASI HC A02/MF A04

The optical communications in satellites and some other optical experiments, require supporting baseplates to attach highly precise and sensitive optical equipments. A concept of baseplate based on a sandwich construction with both, faces and core, made of CFRP (Carbon Fiber Reinforced Plastic) was designed, accomplishing with very stringent requirements as follows: very high dimensional stability (deformations lower than 0.1 micrometers and rotations lower than 0.1 arcsec), very high stiffness to mass ratio (first natural frequency higher than 160 Hz and a total mass lower than 3 Kg), and availability of a great number of hard points to attach the different equipments placed in several configurations. The development test campaign carried out to demonstrate the capabilities of the outstanding baseplate design for high stability applications, the manufacturing activities to get a fully representative first prototype and the initial approach to a complete performances verification program, is presented. ESA

ON THE MECHANICAL DEVELOPMENT OF THE FLEXIBLE EXTERNAL INSULATION (FEI) FOR HERMES SPACEPLANE
J. Bolz *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 277-283 (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

The Flexible External Insulation (FEI) is a thermal protection system which covers large areas of the Hermes spaceplane. Under nominal reentry conditions the thermal loading of these areas is moderate (650 C). Targeting for minimum weight, the fibrous FEI blanket has to ensure that the temperature of the 'cold' Hermes structure remains below 175 C. As critical mechanical design driver the high acoustic loading was identified. This noise results from the boundary layer during ascent of the Ariane 5. Additionally, a dynamic excitation (flutter) of the outer cover fabric of the FEI by the airflow may occur. An overview on the structurally related aspects of the FEI development is presented, concentrating on the performed test program and on the achieved results and their influence on the development process. ESA

DESIGN EVALUATION OF GLARE LAMINATE LAY-UPS

A. I. Pendus, P. T. Elangovan, and P. Minderhoud *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 301-306 (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A02/MF A04

The initial buckling shear strength of flat rectangular panels is determined for various GLARE (Glass Aluminum Reinforced) laminate configurations to evolve an optimum design layup for shear panels. It is shown possible to simplify the laminate anisotropy to special orthotropy for which the readily available solutions for elastic buckling can be employed. If the calculated elastic buckling stresses are above the value of linear limit, a plasticity correction is applied on those stresses. The correction process is iterative; the load redistribution among the layers has to be accounted for as the iteration proceeds. The design evaluation of GLARE laminates entails a number of design parameters such as laminate layup, fiber orientation, panel size, and the type of loading. ESA

JOINTS BETWEEN DISSIMILAR METALLIC AND CERAMIC MATERIALS

David P. Bashford *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 307-314 (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A02/MF A04

The joining of dissimilar metallic and ceramic materials requires an understanding of the implications of dissimilar properties on the integrity of the joint configuration. The joints may be classified in two ways: either fused and permanent or mechanical interconnections, which allow disassembly. Wherever possible, the physical and mechanical properties of the dissimilar materials should be matched as closely as is practically feasible. In particular, stiffness and coefficients of thermal expansion are the most significant properties. The materials of interest include alloys, metal matrix composites, monolithic ceramics, and ceramic and carbon-carbon composites. Where radically different materials need to be joined, then graded structures or functionally gradient materials can provide a realistic means of achieving a transition joint. Integrity and inspection of joints is important and mechanical joints tend to provide greater confidence on these counts than do fused joints. Reference is made to jointing in thrusters and nozzles plus experience with thermal protection systems. ESA

INTRODUCING SMaSE: AN AIDE MEMOIRE ON STRUCTURAL MATERIALS AND SPACE ENGINEERING

Josephine Wilson *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 315-319 (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A01/MF A04

A document produced in response to a need identified by ESTEC, which brings together in one source all those factors which require evaluation by the designers of all space structures, is introduced. It provides basic information on the use of metal alloys and fiber reinforced plastic composite materials and is an 'aide memoire' for the whole design process. It cannot, for reasons of usable size, present a detailed analysis of each topic. However, a comprehensive referencing system directs the reader to the source documents, design guides, manuals, ESA PSS documents, and verification tools, including recognized Test Specifications and nondestructive testing techniques for manufacturing and in-service use. A NEW AND EFFICIENT WAY TO JOIN COMPOSITE PIPES c31

H. Lahtinen, M. Autio, S.-G. Sjolind, and A. Pramila *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 321-324 (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A01/MF A04

Most of the European standards and norms applied by the pressure vessel authorities require testing of the structure by a pressure ten times the design pressure. One of the goals during the course of a referenced work was to show that the burst pressure in fact is ten times the design pressure. All the joints in the structure were of traditional hand laminated butt joint type. Several tests were carried out but the goal pressure was never reached. The reason was always the same: leakage of joints. Because of this, a new type of joint was created. The joint is the cylindrical analogy of a scarf joint. The target pressure was reached during the first test. ESA

PERFORATED PLATES FOR THIN-WALLED STRUCTURES c39

M. Drdacky and J. Lesak *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 333-337 Sponsored by Ministry for Economy and Industries (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A01/MF A04

Perforated plates, that is, plates with a high density of small openings, as a suitable sheet material for thin walled plated structures are presented. Perforations enable to increase a wall thickness of thin walled structures and thus, also, their load carrying capacity at the same material consumption. Results of experimental research concerning the stability behavior of such perforated webs compressed at two opposite edges are described. The influence of the plate thickness, the perforation extent, shapes of holes, and support conditions were studied. A simple semi-empirical method for estimating critical loads of perforated webs is presented. A utilization of perforated webs in search of optimum mass distribution in compressed thin walls is demonstrated. ESA

ADVANCED METHODS OF PERMANENTLY JOINING CARBON MATERIALS c39

L. T. Anikin, A. V. Demin, G. A. Kravetskiy, and V. I. Kostikov *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 339-342 Prepared in cooperation with Nauchno-Issledovatelskii Inst. Grafit USA Corp. and Nauchno-Issledovatelskii Inst. Grafit-Europa G.m.b.H., Germany (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A01/MF A04

The most promising method of joining large sized articles and structures of an intricate configuration is by glueing using high temperature carbonizable adhesives. Due to low hardening temperature (20 to 110 C) of such adhesives, there is no need to use fluxes or protective atmospheres, energy consumption is reduced, the stress problem in the joint is favorably solved, and the serviceability of the joint is ensured at high temperatures in various media. When joining dissimilar materials such as carbon or metal, a serviceable structure can be generally formed by combining different ways of decreasing stresses. On the basis of stressed state investigation in graphite-metal joints, recommendations were developed on the stepwise production of a friction pair involving the preparation of a soldered member having a joint line on the side surface, followed by its welding to a metal case. ESA

CONSTITUTIVE LAWS FOR DESCRIBING THE SERVICE RELEVANT CREEP BEHAVIOUR OF METALLIC MATERIALS **c26**
P. Agatonovic, J. M. Church (Joint Research Centre of the European Communities, Petten, Netherlands.), and R. Hurst (Joint Research Centre of the European Communities, Petten, Netherlands.) *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 355-360 Sponsored by Commission of the European Communities (For primary document see N94-10001 01-24)
Copyright Avail: CASI HC A02/MF A04

The optimum design of a structure for operation in the high temperature creep regime conventionally relies on in-built safety features applied to stress rupture data. As considerable inaccuracy is intrinsic and conservative design inevitable using such design rules, lightweight structures are unlikely to benefit from such an approach. Based on the results of the BRITE P-1209 program, it is demonstrated that advanced modeling methods exhibit significant advantage over conventional methods. Design of lightweight structure involves various aspects which a successful model has to handle; focus is on the two of the most important. The first is the ability to interpolate with confidence between data from a limited high quality data set and the second is the extension potential from uniaxial data to more complex multiaxial stress conditions. Copyright Avail: CASI HC A02/MF A04

A review of activities in the development of high temperature composites for use in aerospace transportation systems is presented. A wide range of temperature is needed for structural materials and for thermal protection. The emergence of thermal resistant fibers like carbon and ceramics was the basis for the development of advanced materials. For very high temperatures up to 2000 C, the use of carbon-carbon is effective and improvement has been achieved regarding coating protection systems in order to face oxidation reaction of carbon above 500C. Oxidation resistant carbon-carbon is currently the baseline solution for the nose cap and the wing leading edges, hottest parts of Hermes, the European Spaceplane. Growing interest has appeared for the use of glass ceramic composites with availability of suitable ceramics fibers (mainly SiC fibers) and potentiality of cost effective processing due to glass ceramic. The objective operating temperature of glass ceramic fibers is above 1000 C and a large area of the outer surface of future winged transportation systems is aimed at as nominal application. ESA

FIBRE OPTIC STRAIN AND TEMPERATURE MEASUREMENT IN COMPOSITE MATERIALS: A REVIEW OF THE OSTIC PROGRAMME **c39**

Brian Culshaw and Craig Michie *In* ESA, Advanced Materials for Lightweight Structures Oct. 1992 p 393-398 Sponsored in part by Commission of the European Communities (For primary document see N94-10001 01-24)

Copyright Avail: CASI HC A02/MF A04

OSTIC (Optical Sensing Technologies for Intelligent Composites) is a recently completed European collaborative project which represents the first concerted effort in Europe on fiber optic sensing technologies for use in carbon and glass fiber reinforced plastic material. The scope of the project embraced both the characterization of material interactions and the derivation of fiber optic sensing techniques for use within these materials. The project demonstrated successfully that optical fibers may be embedded within 1 mm thick composite samples without any degradation in the mechanical performance of the composite panel. Fiber optic sensing in composite materials was also demonstrated showing distributed measurement of dynamic strain over a sample of the order of 1 m in length with linear spatial resolution of the stain measurement of approximately 20 cm. Additionally, the successful simultaneous measurement of temperature and quasi-static strain over similar gauge lengths were experimentally demonstrated. ESA

Innovation is often initiated by research carried out by universities or scientific institutions. Therefore, IOP (Innovation Oriented research Programs) support of these research activities is considered to be of great importance for the industry. Most IOP can be situated at the lower end of the well known S curve which models the generation of technological knowledge. The precompetitive IOP activities include mission oriented fundamental and strategic applied research. IOP are created on selected areas of stategic technology. Their main goals are generation of new technology, enhancement of promising research activities, and clustering of research groups. ESA

In trying to profit from the benefits of aerospace technologies for sporting goods enjoyed by people day by day, a new bi-frame tennis racket '2-rac' was developed. Mainly to minimize potential problems with the tennis elbow and to optimize playing characteristics, some basic questions were addressed and carefully answered in to what is and should be a tennis racket, prior to studying the state of the art and the market conditions. From problem reduction, an idea and consequent step by step solution technique with proof of concept analysis, handmade functional models, many simple then more detailed computer simulations, and also high speed camera tests, the final acceptable solution was obtained. The remaining problem was to overcome optical and real weight restrictions by a super lightweight design. Problems and steps are summarized. ESA

A computer program for creating composite structures with prescribed thermomechanical properties is presented. The problem of this type can be called an inverse one. The problem is formulated as a constrained nonlinear minimization problem where ply orientations and/or thicknesses are selected to be design variables. The formulation of the inverse problem and the laminate theory used are described. The prescribed thermomechanical properties are used as objective function and constraints, and the values of the properties are derived from the classical lamination theory. ESA

SILICON-BASED ELEMENTARY PARTICLE TRACKING SYSTEM: MATERIALS SCIENCE AND MECHANICAL ENGINEERING DESIGN

W. O. Miller, M. T. Gamble, T. C. Thompson, and J. A. Hanlon 1993 9 p Presented at the 9th International Conference on Composite Materials, Madrid, Spain, 12-16 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract W-7405-eng-36)

(DE93-012630; LA-UR-93-1162; CONF-930758-1) Avail: CASI HC A02

Research and development of the mechanical, cooling, and structural design aspects of a silicon detector-based elementary particle tracking system has been performed. Achieving stringent system precision, stability, and mass requirements necessitated the use of graphite fiber-reinforced cyanate-ester (C-E) resins. Mechanical test results of the effects of butane, ionizing radiation, and a combination of both on the mechanical properties of these materials are presented, as well as progress on developing compression molding of an ultralightweight graphite composite ring structure and TV holography-based noninvasive evaluation. EVALUATION OF TEST SPECIMEN SHAPE EFFECTS ON THE FLEXURAL FATIGUE OF CFRP LAMINATES [CHOKKOU SEKISOU CFRP NO MAGE TSUKARE SHIKEN NIOKERU SHIKENHEN KEIJOU NO HYOUKA NI KANSURU KENKYUU]

Yoshio Noguchi May 1992 19 p In JAPANESE

(NAL-TR-1159; JTN-93-80443; DE93-793622) Avail: CASI HC A03/MF A01

The flexural fatigue behavior and strength characteristics of cross-ply Carbon Fiber Reinforced Plastic (CFRP) laminate composites were investigated using three different PolyAcryloNitrile (PAN) based carbon fiber composite test specimens, i.e., Medium Strength (MS), InterMedium Strength (IMS), and High Strength (HS) types. Flexural fatigue tests employed four-points plane bending operations under a complete reversal frequency of 30 Hz. The effects of using test specimens having a coupon or side-curved shape were experimentally evaluated, with flexural fatigue strength results indicating that IMS and HS cross-ply CFRP laminates are effected more by the shape and generally have a greater S-N (Stress amplitude versus Number of cycles to failure) curves in the slope than MS ones. After being subjected to 10(exp 7) cycles, the resultant ratio of flexural fatigue strength to static flexural strength was found to be 0.50, 0.42, and 0.40 for MS, IMS, and HS cross-ply CFRP laminates, respectively. TRIBOLOGICAL CHARACTERISTICS OF HOT-PRESSED SELF-LUBRICATING COMPOSITES [HOTTOPURESU HOU DE SAKUSEISHITA JIKO JUNKATSUSEI FUKUGOU ZAIRYOU NO TORAIBOROJI TOKUSEI NI KANSURU KENKYUU]
Mineo Suzuki and Makoto Nishimura May 1992 51 p In JAPANESE
(NAL-TR-1160; JTN-93-80444; DE93-793623) Avail: CASI HC A04/MF A01

Tribological characteristics of hot-pressed self-lubricating composites were investigated to develop new high performance tribo-materials for space applications. The composites consisted of molybdenum disulfide (MoS2), refractory metal oxide (MoO3, MoO2, WO3, WO2, Ta2O5, or Nb2O5), and refractory metal (Mo, W, Ta, or Nb). Friction tests were performed in a vacuum, in nitrogen, and in air atmospheres using ring-on-disk type friction testers. The best material composition under the applied test conditions (contact pressures of from 0.5 to 4 MPa and sliding speeds of from 0.11 to 0.55 m/sec) was found to be composition of MoS2 80 percent plus MoO2 10 percent plus Nb 10 percent. In a vacuum, this composite showed a coefficient of friction of less than 0.07 and a specific wear rate of less than 10(exp -11) cu mm/(N x mm). Good tribological performance was also obtained with composition of MoS2 80 percent plus Nb2O5 10 percent plus Nb 10 percent, MoS2 80 percent plus MoO2 10 percent plus Mo 10 percent and MoS2 80 percent plus MoO2 20 percent. For the composites showing good tribological performance, a thin, uniform transfer film was formed on the steel ring surface. X-ray diffraction results showed that Mo2S3 was present in almost all the composites, thereby, suggesting that MoS2 partially dissociated into Mo2S3 during the hot-press process. It was also found that the addition of the refractory metal oxide and/or metal promoted both the dissociation of MoS2 and the chemical reaction among the involved species. Author (NASDA)

RESPONSE OF COMPOSITE LAMINATES TO DYNAMIC SURFACE LOADS Ph.D. Thesis
Shyh-Shiuh Lih 1992 200 p
Avail: Univ. Microfilms Order No. DA9310963

The quantitative features of the elastodynamic field produced in unidirectional and multilayered graphite/epoxy composite laminates by surface loads are studied. Each layer is assumed to be transversely isotropic and dissipative with arbitrarily oriented symmetry axis, and characterized by five complex and frequency dependent constants. The dissipative property of the material is modeled approximately through the introduction of a frequency dependent damping function. A new nondestructive ultrasonic technique is developed for the determination of the material constants. A multiple transform technique involving time and spatial Fourier transforms is used to formulate the response problem due to a transient surface load. A global matrix method is used to solve the resulting boundary problem; the solution for a half space with the same loading conditions is obtained as a special case. The integrals involving the spatial inverse transforms are evaluated by a modified version of the Clenshaw-Curtis quadrature scheme for the two dimensional problem and by an adaptive surface-fitting integration scheme for the three dimensional problem. Time inversion is carried out by means of the Fast Fourier transform (FFT) algorithm. The response of a laminate to different transient loads including concentrated loads and distributed loads is presented. In addition, approximate solutions based on the classical plate bending theory and the modified shear deformation plate theory are obtained and the range of validity of the approximate solutions are determined through comparison with the exact results. The multiple transform technique is shown to be a practical alternative to finite element and other numerically intensive computational schemes for wave-field calculations in composite laminates. FIBRE REINFORCED POLYMER MATRIX COMPOSITES: MICROSTRUCTURE AND MECHANICAL PROPERTIES [FASERVERBUNDWERKSTOFFE MIT POLYMERMATRIX: AUFBAU UND MECHANISCHE EIGENSCHAFTEN]
Karl Schulte May 1992 317 p In GERMAN Sponsored by DFG
(DLR-FB-92-28; ETN-93-93959) Avail: CASI HC A14/MF A03; DLR, Zentrale Allgemeine Dienst, Versand, Postfach 90 60 58, 5000 Cologne, Germany, HC

The increasing interest in fiber reinforced polymer composites for technical application because of their superior properties, which requires a deepened knowledge of their microstructure and mechanical properties, is addressed. Based on a literature survey and investigations, an overview is given concerning the microstructure of composites. The influence of the microstructure on the mechanical properties under static and fatigue loading is given, together with the various damage mechanisms that occur. While the various damage mechanisms that occur during loading can be described quite sufficiently, there remains a lack in knowledge and understanding of what finally determines composite failure. Via a systematic description of composite damage mechanisms, an attempt to understand the interactions that lead to composite failure is made. Various nondestructive and destructive test methods to detect damage mechanisms are introduced. ESA

DAMPING MECHANISMS IN CHEMICALLY VAPOR DEPOSITED SIC FIBERS
James A. DiCarlo and Jon C. Goldsby Jul. 1993 11 p Presented at the International Symposium on Damping of Multiphase Inorganic Materials, Chicago, IL, 2-5 Nov. 1992; sponsored by PMCC
(RTOP 510-01-50)
(NASA-TM-106334; E-7697; NAS 1.15:106334) Avail: CASI HC A03/MF A01

Evaluating the damping of reinforcement fibers is important for understanding their microstructures and the vibrational response of their structural composites. In this study the damping capacities of two types of chemically vapor deposited silicon carbide fibers were measured from -200 C to as high as 800 C. Measurements were made at frequencies in the range 50 to 15000 Hz on single cantilevered fibers. At least four sources were identified which contribute to fiber damping, the most significant being thermoelastic damping and grain boundary sliding. The mechanisms controlling all sources and their potential influence on fiber and composite performance are discussed. Author (revised)

INTERFACE CONSIDERATIONS IN Al2O3/NiAl COMPOSITE Final Report
Ajay K. Misra Jul. 1993 33 p
(Contract NAS3-25266; RTOP 510-01-50)
(NASA-CR-191167; E-8032; NAS 1.26:191167) Avail: CASI HC A03/MF A01

The fiber-matrix interface requirements in an Al2O3/NiAl composite were examined from theoretical considerations. Several factors that influence the interface bonding requirements were analyzed. These include: (1) residual stresses due to fiber-matrix coefficient of thermal expansion (CTE) mismatch; (2) matrix cracking stress at room temperature; (3) fracture toughness at room temperature; (4) load transfer from the matrix to the fiber and ultimate tensile strength at the use temperature; and (5) creep resistance at high temperature. A relatively weak fiber-matrix bond, with an interfacial shear strength of approximately 15-20 MPa, might be sufficient for attaining the desired mechanical properties in the fiber direction at the use temperature. A weak fiber-matrix bond is also beneficial for increasing the fracture toughness of the composite at room temperature. In contrast, a strong fiber-matrix bond is required to withstand some of the residual stresses resulting from the fiber-matrix CTE mismatch, which are not likely to be reduced significantly by interface coatings. A relatively strong bond is also beneficial in increasing the matrix cracking stress at room temperature. Various interface coating options to accommodate the conflicting bonding requirements were reviewed. One viable coating option is to incorporate a thick, ductile interface layer well bonded to both the fiber and the matrix. Author (revised)

DRY IN-LINE THERMOPLASTIC MATRIX IMPREGNATION, PHASE 1 Final Report, Aug. 1992 - Jan. 1993
L. S. Duncan Apr. 1993 49 p
(Contract DAAL04-92-C-0011)
(AD-A265016; NCI/93-07-Phase-1; ARL-CR-55-Phase-1) Avail: CASI HC A03/MF A01

The objective of this program is to develop an in-line thermoplastic impregnation module which can be used with existing automated manufacturing systems, such as filament winding equipment, which were originally designed for use with thermoset materials. During Phase 1, the ability to melt impregnate non-woven glass tow with polyphenylene sulfide (PPS), nylon, and polycarbonate resins has been demonstrated at the breadboard level by using a laboratory injection molding press to feed resins to a melt coating module. The tow was preheated prior to coating by means of a convection heating tunnel. Key parameters governing melt penetration included incoming tow temperature and melt viscosity. Further development of the process would allow the creation of composite shapes and structures which could be post processed by thermoforming techniques and would have the desirable performance characteristics of thermoplastics such as damage tolerance (impact resistance) and repairability. This paper addresses the application of ultrasonic sensing to damage assessment in ceramics and ceramic matrix composites. It focuses on damage caused by thermal shock or oxidation at elevated temperatures, which often results in elastic anisotropy. This damaged-induced anisotropy is determined by measuring the velocities of ultrasonic waves in different propagation directions. Thermal shock damage is assessed in ceramic samples of reaction bonded silicon nitride (RBSN). Thermal shock treatment from different temperatures up to 1000 C is applied to produce the microcracks. Results indicate that most microcracks produced by thermal shock are located near sample surfaces. Ultrasonic measurements using the surface wave method are found to correlate well with measurements of degradation of mechanical properties obtained independently by other authors using destructive methods. Oxidation damage is assessed in silicon carbide fiber/reaction bonded silicon nitride matrix (SCS-6/RBSN) composites. The oxidation is done by exposing the samples in a flowing oxygen environment at elevated temperatures, up to 1400 C, for 100 hr. The Youngs' modulus in the fiber direction as obtained from ultrasonic measurements decreases significantly at 600 C but retains its original value at temperatures above 1200 C. This agrees well with the results of destructive tests by other authors. On the other hand, the transverse moduli obtained from ultrasonic measurements decrease continually until 1200 C. Measurements on the shear stiffnesses show behavior similar to the transverse moduli. The results of this work show that the damage-induced anisotropy in both ceramics and ceramic matrix composites can be determined successfully by ultrasonic methods. This suggests the possibility of assessing damage severity using ultrasonic techniques. Author (revised)

IONIZATION POTENTIALS OF SMALL CARBON CLUSTERS Technical Report, Sep. 1991 - Aug. 1992
Ragulan Ramanathan, Jeffrey A. Zimmerman, and John R. Eyler 5 May 1993 30 p Prepared in cooperation with IBM Technology Lab., Endicott, NY Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-87-J-1248)
(AD-A264379; TR-40) Avail: CASI HC A03

Ionization potentials (IP's) of small carbon clusters (C(sub n), n = 3-6) have been bracketed with an uncertainty of a few tenths of an eV by charge-transfer methods in a Fourier transform ion cyclotron resonance mass spectrometer. Values obtained are compared to previously determined experimental and theoretical values. Several interesting reactions other than charge-transfer were observed between the carbon cluster ions and the charge-transfer reference compounds. The products of these reactions are reported and discussed. DTIC

AN ANALYSIS OF FIBER-MATRIX INTERFACE FAILURE STRESSES FOR A RANGE OF PLY STRESS STATES
J. H. Crews, R. A. Naik (Analytical Services and Materials, Inc., Hampton, VA.), and S. J. Lubowinski Jul. 1993 43 p
(RTOP 505-63-50-04)
(NASA-TM-108999; NAS 1.15:108999) Avail: CASI HC A03/MF A01

A graphite/bismaleimide laminate was prepared without the usual fiber treatment and was tested over a wide range of stress states to measure its ply cracking strength. These tests were conducted using off-axis flexure specimens and produced fiber-matrix interface failure data over a correspondingly wide range of interface stress states. The absence of fiber treatment, weakened the fiber-matrix interfaces and allowed these tests to be conducted at load levels that did not yield the matrix. An elastic micromechanics computer code was used to calculate the fiber-matrix interface stresses at failure. Two different fiber-array models (square and diamond) were used in these calculations to analyze the effects of fiber arrangement as well as stress state on the critical interface stresses at failure. This study showed that both fiber-array models were needed to analyze interface stresses over the range of stress states. A linear equation provided a close fit to these critical stress combinations and, thereby, provided a fiber-matrix interface failure criterion. These results suggest that prediction procedures for laminate ply cracking can be based on micromechanics stress analyses and appropriate fiber-matrix interface failure criteria. However, typical structural laminates may require elastoplastic stress analysis procedures that account for matrix yielding, especially for shear-dominated ply stress states. Author (revised)

CREEP DEFORMATION AND MECHANICAL PROPERTIES OF SINTERED GLASS AND POLYCRYSTALLINE MATRIX COMPOSITES Ph.D. Thesis
Rollie Eugene Dutton 1992 126 p
Avail: Univ. Microfilms Order No. DA9311026

It was observed that the free sintering of ceramic particulate composites is reduced significantly, even at modest volume fractions of the dispersed inclusions. The decrease in the sintering rate might reside in a decrease in the driving force for sintering, a modification of the kinetic factors, or a combination of these. Realistic physical models indicate that the reduction in the driving force is small. The first task of the research was to determine how dispersed inclusions influenced the creep viscosity of the composite. The results of this phase of the research are described. The effect of spherical nickel inclusions on the sintering, creep, and electrical conductivity of a glass matrix composite was investigated. Glass was chosen as the matrix phase in order to eliminate the complications of grain growth. The effects of zirconia inclusions on the sintering and creep of a polycrystalline matrix (for which grain growth occurs) are reported. A combination of this work and other studies indicated that the main factors responsible for the sintering difficulty are the packing of the matrix phase and interactions between the inclusions. A method for alleviating the difficulty associated with these factors was developed and used to form particulate composites with nearly full density. The second task of this research was to measure the mechanical properties of the composites formed by the improved method and to compare the data with those for similar composites formed by more conventional methods. The mechanical properties of the sintered composites are reported. Dissert. Abstr.

Performance of aircraft structures has progressed in a sequence of steps during the past. Since composite materials have gained broad application because of significant technological improvement, it is timely to look for the next step in improvement of aircraft performance. It is very likely that this step is related to smart structures technology. Smart structures technology is able to meet various aircraft design objectives such as improved military aircraft effectiveness through improved aircraft capabilities and reduced life cycle cost or reduced direct operating cost of civil aircraft through improvement in performance, fuel consumption, and aircraft maintainability. Active/adaptive structures, structure health monitoring, and structure integrated avionics are the three areas which are felt to be the areas where smart structures technology is most beneficial. Ways for cooperation between various engineering and natural sciences, being a major driving force for the success of smart structures, are described as well as some laboratory scale experiments which were recently performed. It is felt that an increased effort in engineers in various fields towards realization of smart structures can be a new rewarding challenge for the aircraft industry in developing next generation aircraft. A modal analysis study, representing one of the anticipated 'Cooperative Spacecraft Structural Dynamics Experiments on the NASA Langley CSI Evolutionary Model', was carried out as a sub-task under the NASA/DLR collaboration in dynamics and control of large space systems. The CSI evolutionary testbed (CEM) is designed for the development of Controls-Structures Interaction (CSI) technology to improve space science platform pointing. For orbiting space structures like large flexible trusses, new identification challenges arise due to their specific dynamic characteristics (low frequencies and high modal density) on the one hand, and the limited possibilities of exciting such structures and measuring their responses on orbit on the other. The main objective was to investigate the modal identification potential of several different types of forcing functions that could possibly be realized with on-board excitation equipment using a minimum number of exciter locations as well as response locations. These locations were defined in an analytical test prediction process used to study the implications of measuring and analyzing the responses thus produced. It turned out that broadband excitation is needed for a general modal survey, but if only certain modes are of particular interest, combinations of exponentially decaying sine functions provide favorable excitation conditions as they allow to concentrate the available energy on the modes being of special interest. From a practical point-of-view structural nonlinearities as well as noisy measurements make the analysis more difficult, especially in the low frequency range and when the modes are closely spaced. Copyright Avail: CASI HC A03/MF A04

A major improvement of helicopter performance and comfort can be achieved by the implementation of rotor active control technology (RACT). The introduction of individual blade control (IBC) is a subject of current research activities. But the breakthrough of this technology is still missing due to the lack of appropriate rotating blade actuation systems. Smart materials may open a new possibility for the realization of rotor active control. A survey of current hydraulic individual blade actuation systems shows that these are very complicated and heavy. Blade actuation by smart materials offers the change for an electrical system integrated into the blade itself. A study of different blade actuation systems shows that in principle there is the possibility of achieving this goal. But, today the available materials are not ready for real 'smart' applications. The preferred materials - piezoceramics - show a too low tension strength and very low active strains. Therefore, at this time the only feasible blade actuation system for individual blade control seems to be a hinged flap at the outer third of a rotor blade. This flap can be controlled by a smart (piezoelectric) actuator. Estimations show that such a system will work on the desired yaw. Author (revised)

There have been a large number of technologies described whose purpose is to aid in the control of composite manufacture. The aim of this paper is to readdress the requirements of composite manufacture to assess which features of the various techniques are best suited to providing improved processing. To start with, the requirements of quality in manufacture and the hidden costs associated with incorrect processing are considered. This will allow us to rank the aspects of processing which it would be attractive to improve. Following this, a range of monitoring processes and their ability to deliver on these improvements and at what cost in terms of expense and complexity are considered. Monitoring processes considered include fiber-optic (optical) methods, dielectrometry, and ultrasonic methods. Author

Aastra Advanced Ceramics is a major manufacturer of piezoelectric ceramic materials. Aastra Aerospace is involved in the development of smart structures technology based on these materials. Piezoelectric ceramics as actuators offer high mechanical stiffness, large output stress, and good linearity. As strain sensors, piezoceramics offer very high sensitivity. Initial research into the use of externally-bonded or embedded piezoceramic strain sensors and actuators has lead to the development of in-line sensor-actuator systems for use in truss-type smart structures. The target applications for these units are large flexible space structures, but the technology is applicable to earth-based truss structures as well. Similarly, Aastra is investigating the use of piezoelectric materials for the active damping of aircraft structures, with the goal of reducing structure-borne cabin noise with minimum additional weight. The development of Aastra's piezoceramic research activities and an overview of present work in the field of smart structures is presented. Author (revised)

Structurally integrated fiber optic sensors (SIFORS) will form a necessary part of future Smart Structures and strain sensing will provide valuable information on the use and loading of such structures and also determine the response of the structure to these loads. Strain measurements may be used to check structural integrity and in the case of Smart Adaptive Structure they would provide the deformation information required by the structurally integrated actuation control system. Continuous monitoring of the applied loads could also be used to determine the actual fatigue life of the structure at any point in its operation. In the case of composite materials improved quality control during fabrication may be possible from such a built-in sensing system and this could lead to a more consistent and reliable product. Overall the introduction of an embedded fiber optic strain sensing system to composite structures may enhance confidence in their use and lead to an expansion in the range of application, especially as primary structures in the aerospace field. The types of fiber optic sensors are reviewed and it is shown that the intracore Bragg grating and the intrinsic Fabry-Perot interferometer appear to qualify for continued consideration as the universal sensor for the broad range of potential Smart Structures. The key elements of strain sensing with both types of structurally integrated fiber optic sensors are reviewed and issues such as thermally induced apparent strain are discussed. It is shown that although both sensors now have good methods of demodulation, the Bragg grating sensor has the greatest potential to satisfy the requirements demanded of the ideal sensor for Smart Structures due to the recently developed radiometric wavelength demodulation system. This system promises the fabrication of a robust, simple, absolute measurement, low cost multisensor system that could be integrated onto an optoelectronic chip that can form part of the interface to any structure and in essence solve the critical interconnect problem. Two important questions, however, remain to be addressed: can the intracore Bragg grating sensor perform all of the tasks required, and can Bragg gratings of 'sufficient quality' be fabricated in an automated process. Shape memory materials form one group of 'smart materials' which are of current interest. The sensing and actuating performance of these shape memory materials have been used in diverse industrial applications. These applications involve either the one-way or two-way effect, pseudoelasticity, recovery forces or damping characteristics of the SM-alloy. Each of these characteristics is associated with its unique response to thermal-mechanical forces. Besides these material parameters, the operating conditions and design parameters have to be taken into account when structures, in which SM elements are incorporated, are to be considered. The processing as well as subsequent operating conditions are relevant to the reproducible

(stable) behavior and life time of the material and are discussed.

Shape memory alloy wire 'tendons' can be used as embedded actuator elements to control the level of facesheet strain in adaptive structural components which utilize sandwich panel construction. As facesheet strain is varied, the degree of curvature and magnitude of tip deflection of a panel section can be controlled. Methods for modeling and conditioning shape memory materials and their subsequent integration into composite structures are described along with related control system and feedback sensor development. Finally, an adaptive antenna application employing 'flex-biased' actuation and an attitude control surface based on 'antagonistic' actuation are described. Author (revised)

Piezoelectricity will be defined phenomenologically and discussed pictorially to underscore the distinction between single crystal piezoelectrics and the poled ceramics which form the basis for most practical sensor and actuator systems. The classical lead zirconate: lead titanate (PZT) family is the most widely used. Recent advances in the understanding of the conventional morphotropic phase boundary (MPB) compositions are discussed with particular emphasis upon the nature and the control of fatigue at high strain levels. Phase switching compositions in the lead zirconate stannate titanate PZSnT system exhibit very high switching volume strain, shape memory, and controlled induced piezoelectric response. Electrostrictors in the lead magnesium niobate: lead titanate and lead lanthanum zirconate titanate (PMN:PT and PLZT) families form most interesting spin glass states at lower temperature in which precise reproducible elastic strain may be induced by electric field. In PMN:PT the strain is free from aging and other domain related problems, the thermal expansion is very low, and these materials are ideal for very precise actuation. Polarization biased electrostrictors have exceedingly high induced piezoelectric d(sub 33), d(sub 31), and d(sub h) coefficients and can be used as agile transducers in which both the magnitude and phase of the response is under DC field control. Both spin glass and phase switching systems can be tuned in composition to optimize performance at 100 K and provide low power 'dial-a-displacement' capability. Recent advances in the fabrication of highly perfect thin films of PZT type compositions on silicon, by both vapor and liquid phase techniques provides a new high force electromechanical power source for microelectromechanical (MEMS) systems. The current status of the evaluation of electromechanical response in PZT, PMN:PT and PbSnZT thin films on silicon is briefly reviewed and possible applications in MEMS systems discussed. Aircraft are known to be highly complex systems requiring an extensive amount of monitoring because of their safety criticality. To reduce direct operating or life cycle cost a lot of effort was spent on automated monitoring systems. On-board loads monitoring systems for aircraft as well as built in test equipment in avionics systems are already available nowadays. On-board loads monitoring systems however do not monitor damage in-situ and on-board. This still has to be performed on-ground by manual nondestructive testing (NDT) inspection. Smart structures technology is a means which can support development towards automated in-situ monitoring of damage even on-board the aircraft. The paper starts with a brief view on aircraft maintenance cost, describes existing aircraft health and usage monitoring systems as well as NDT procedures, and explains how these procedures could be combined to a smart system using smart materials and structures technology. A strategy is proposed how gradual introduction of smart structures technology into structure health monitoring systems can make this new technology beneficial for aircraft operators in short term.

Structural health monitoring on military aircraft is currently carried out via strain gauges attached to the surface of the aircraft structure. A parametric system based exclusively on flight parameters is being developed for use on EFA. Both of these systems monitor the airframe fatigue life. With the emergence of Smart Structures technology, a new method of structural health monitoring is feasible that has perceived advantages over the current technology. How fiber optics embedded within a composite laminate can be used to monitor strains within the aircraft structure, and hence its fatigue life is described. Embedded fiber optics can be used to monitor sustained damage - battle or low velocity impact damage, give a full flight history and, with diagnostic capability, unconditioned maintenance would be available. Composite materials offer tremendous benefits for engineering applications and are now specified for use in several safety critical structures. However, despite extensive materials research and development, they do have a number of areas where their behavior is still not fully understood. This is particularly so with the more complex mechanical parameters in larger structures. Current structural design attempts to allow for these unknowns by over-designing, extensive testing, and frequent inspection. Embedded optical fiber sensors offer the potential to monitor many of these parameters, and are additionally of a similar physical and mechanical nature to the reinforcement fibers used in advanced composites. Westland Aerospace was involved in the development of fiber sensors for composite monitoring for over five years, and pioneered the application of embedded fiber sensors in thermoplastic composites during earlier joint research projects with the United Technologies Research Center. Previous programmers showed that research and development into both optical fiber sensors and materials is a key to the success of 'smart structures' technologies. The BRITE sponsored Optical Sensing Techniques in Composites (OSTIC) program represents the largest European research program to date. Similar research is underway at several centers worldwide, mainly in the USA and Canada. It was decided to set up a joint sensors/materials project under the UK Government supported LINK Structural Composites collaborative research program. The project will be performed by Westland Aerospace and the Optical Fibre Sensors Group at the UK Optoelectronics Research Centre. Factors relating to the development and application of optical fiber strain sensors for the monitoring of composite structures, and in particular the factors relating to the embedding of these optical fibers in composite laminates are addressed. The requirements of a fiber-optic strain sensor system for aircraft smart structures are outlined, and an experimental system developed by Canadian Marconi Company for this application is reported. Fiber-optic strain sensors were mounted on an aircraft undergoing full-scale durability and damage tolerance tests, the results of which are presented. Tests were also carried out to verify the response of fiber-optic sensors to acoustic impulse signals. Input signals, similar to the ones encountered in damaged materials under stress, were used to evaluate the response of the sensor to bulk, surface, and plate waves. This was done in order to assess the performance of fiber-optic sensors employed in the acoustic detection of damage in materials. Author (revised)

Digital filters can easily be used to alter signal flows. As long as the desired transfer function of the filter is causal, a great variety of responses is made possible by appropriate choice of filter coefficients. To make use of this property in vibration control, algorithms should automatically change the filter coefficients to meet any given objective. A class of adaptive algorithms which search the gradient of a given performance function is described. In order to illustrate the requirements of adaptive structures, such as structurally conformed design, the feed-forward control environment serves as an example for applying these algorithms. New finite elements which allow for the analysis and optimization of adaptive structures are presented. Two finite elements accounting for integrated piezo-electric devices are formulated: a shell element for the analysis of shallow shell structures with piezo-electric polymers bonded to the surfaces and a truss element with an integrated piezo-electric ceramic. Test cases are presented to illustrate the potential of the finite elements. The shell element is used to compute the vibration excitation of a thin plate as well as the vibration control of a cantilever beam. The truss element is applied to the problem of optimal actuator placement in adaptive truss structures. For the solution of this problem, objective functions for the minimization of the control effort and the spillover energy are formulated. The second part is concerned with the finite element analysis of the behavior of shape memory alloys. A non-linear one-dimensional finite truss element and a non-linear beam element are used for the analysis of a composite beam with embedded shape memory alloy wires, of which the temperature is varied in order to tune the eigenfrequencies. Initial flight tests of a fiber-optic strain gauge (OSG) based on a double-polarization Michelson interferometer with incremental readout via fringe counting were performed. The passive quadrature demodulation technique allows for balanced interferometer arms, exhibiting partial self temperature compensation. A bent reference (R) arm approach for the sake of isolation of the R-arm from the strain to be measured was tested for the first time. The sensor was surface adhered on a carbon fiber reinforced plastic plate which, in turn, was screwed to the main wing spar of a Cessna C207A aircraft. Strain was measured under different flight conditions and compared to the readout of a conventional resistive strain gauge (ESG). Good agreement with the theoretical predictions as well as with the readout of the ESG was observed for short term (of the order of minutes) quasistatic strain measurements despite large vibration induced noise. The Fourier spectra of the time series exhibited also good agreement between ESG and OSG with respect to the dynamical response up to at least 250 Hz. The measurement range and stability of the present experimental setup is limited by polarization instabilities which partly are due to anisotropic transverse stress effects at the adhered fiber sections. Longer term dc strain measurements require carefully controlled isotropic adhesion conditions and miniaturized optomechanical components with improved mechanical stability. Author

The findings of an investigation conducted under the auspices of The Technical Cooperation Program (TTCP) to assess the impact of active controls technology on the structural integrity of aeronautical vehicles and to evaluate the present state-of-the-art for predicting loads caused by a flight-control system modification and the resulting change in the fatigue life of the flight vehicle are summarized. Important points concerning structural technology considerations implicit in applying active controls technology in new aircraft are summarized. These points are well founded and based upon information received from within the aerospace industry and government laboratories, acquired by sponsoring workshops which brought together experts from contributing and interacting technical disciplines, and obtained by conducting a case study to independently assess the state of the technology. The paper concludes that communication between technical disciplines is absolutely essential in the design of future high performance aircraft. Author (revised)

The general equations for a multi-body space system with internal control forces are written. Single body, or 'local', equations of motion are written and then they are transformed into global equations, associated with a sufficient number of 'internal' equations describing the relative motions of the various parts of the system. In such a transformation, quantities of two orders of magnitude arise: the first group is associated with the Earth's equatorial radius, and the second group is associated with a characteristic length of the spacecraft. The two groups are separated in order to avoid round-off errors. Furthermore, a law of control associated with deformations of the connections between the elements of the system is introduced, in such a way that efficient control of instability phenomena may be possible. Numerical examples complete the work. Author

For several years, the Air Force Wright Laboratory has been investigating smart structures technologies. Smart structures incorporate active materials into structural components. Active materials either sense their environment or change in response to an external stimulus or both, and also should be able to carry loads. A smart structure is thus capable of sensing and/or reacting to its environment. Smart structures research at Wright Laboratory has mainly concentrated on aircraft sensory structures and multi-functional structures, such as integrated antennae (i.e., smart skins). Several major programs were initiated to apply and demonstrate these technologies. Recently, the ability of active materials (piezoceramics, for example) to control aircraft structures for improved performance and longevity, has received attention as well. The smart structures technologies are categorized as sensory, active, or multi-functional. The current state of the art for each area and programs aimed at exploiting smart technologies for aircraft applications are described. Gaps in the current technology are identified.

Active control of an aircraft landing gear can give improved passenger ride quality during take-off and landing. The active control system studied uses feedback from airframe mounted sensors to modify rigid body and structural response. The system is based primarily on modifying the damping characteristics in the nose gear oleo. This is achieved by reducing the damping orifice area, with active control of the area about this new datum value. In addition, the benefits of a fully active nose gear using a separate supply of high pressure hydraulic fluid are evaluated. Significant benefits are demonstrated with the active damping control system compared with the basic landing gear. Responses to general runway roughness and discrete runway bumps are considered. The active damping control system is shown to be effective in reducing peak and rms passenger normal accelerations at all fuselage stations, particularly nose and tail. Good improvement can be obtained from active damping control of the nose gear, with no modification to the main gear. The first fuselage bending mode response can be reduced by active damping control. The benefits from the fully active system are marginal, considering the additional system complication. These effects are illustrated for a typical transport aircraft configuration.

Flexible wing technology was explored in a number of design studies. Wind tunnel experiments generally affirm the results of these studies that a flexible, variable twist wing holds the potential for dramatic air vehicle performance improvements. However, the attendant control reversal, increase in control parameter nonlinearities, and the need for an active control system to suppress flutter has discouraged the application of this technology in production designs. Advancement of a robust control capability for damping structural modes; embedded sensors to provide required inputs to the control system for active flutter control and, possibly, battle damage tolerance; high-speed on-board computation; and other technologies promise the capability to exploit the benefits promised by more flexible structures. Current proposals to reduce air vehicle structural weight are briefly reviewed and implications on the control system are assessed. Even though control system concerns exist, they are resolvable and it may be timely to undertake the development and demonstration of an actively controlled flexible wing.

HIGH-TEMPERATURE CORROSION OF CERAMIC-CERAMIC COMPOSITES IN A WASTE INCINERATOR ENVIRONMENT
J. R. Keiser, J. I. Federer, T. J. Henson, and D. L. Hindman (Babcock and Wilcox Co., Lynchburg, VA.) Jan. 1993 60 p
(Contract DE-AC05-84OR-21400)
(DE93-012430; ORNL/M-12212) Avail: CASI HC A04/MF A01

Three types of ceramic composite were exposed to the flue gases of a hazardous waste incinerator to assess their corrosion behavior. One composite consisted of continuously wound filaments of Al2O3-23 wt % ZrO2 in an alumina matrix. This composite was tested, both uncoated and coated, with zirconia on the outer surface. The second composite type consisted of the same fiber but in a zirconia matrix. The third composite consisted of an alumina matrix strengthened with silicon carbide particles. Tubes of these materials were exposed in the waste incinerator at about 900 C for up to six months. Two principal results of exposure were revealed by optical microscopy and electron microprobe examinations: flue gas constituents either penetrated the uncoated alumina matrix of the filament-wound composite, apparently through porosity in the matrix, or deposited on the surfaces of the other composite types where reaction and bonding occurred. Neither event caused significant microstructural degradation although the reaction in the composite with a zirconia matrix suggests that degradation could be a problem under more severe conditions. Apparently, the concentration of penetrating species was too small to form a significant amount of new compounds that could cause degradation within the alumina matrix of the filament-wound composite, and the temperature was too low for the deposits on the surface of the other two types of composites to react significantly with the materials during the longest exposure of 6 months. The zirconia coating on the alumina matrix composite was not adherent enough to permit an assessment of its effect. DOE

STRAIN CONCENTRATION ASSESSMENT OF LAMINATES SUBJECTED TO LOW VELOCITY IMPACT Final Report
Robert F. Anastasi and Steven M. Serabian Apr. 1993 20 p
(AD-A264497; ARL-TR-91) Avail: CASI HC A03/MF A01

Low velocity impact upon composite laminates can lead to both apparent and non-apparent damage zones that result in structural strain concentrations. The strain concentrations can be, or grow to be, larger than permissible design levels through static or cyclic loading conditions. This can drastically reduce the structural integrity of the composite component. In this paper, glass/epoxy composite coupons in three laminate orientations were damaged by low velocity impact that create a damage zone consisting of local fiber breakage and delamination. Conventional moire was then used to measure strain concentration as a function of applied tensile load. Correlations were made between impact energy, delamination area, strain concentration, and laminate orientation. DTIC

PROPERTY CHANGES INDUCED BY THE SPACE ENVIRONMENT IN COMPOSITE MATERIALS ON LDEF: SOLAR ARRAY MATERIALS PASSIVE LDEF EXPERIMENT A0171 (SAMPLE)
Apr. 1993 18 p
(Contract NAS8-38978)
(NASA-CR-192572; NAS 1.26:192572) Avail: CASI HC A03/MF A01

Surface modifications to composite materials induced by long term exposure in low earth orbit (LEO) were dominated by atomic oxygen erosion and micrometeoroid and space debris impacts. As expected, calculated erosion rates were peculiar to material type and within the predicted order of magnitude. Generally, about one ply of the carbon fiber composites was eroded during the 70 month LDEF experiment. Matrix erosion was greater than fiber erosion and was more evident for a polysulfone matrix than for epoxy matrices. Micrometeoroid and space debris impacts resulted in small (less than 1mm) craters and splattered contaminants on all samples. Surfaces became more diffuse and darker with small increases in emissivity and absorption. Tensile strength decreased roughly with thickness loss, and epoxy matrices apparently became slightly embrittled, probably as a result of continued curing under UV and/or electron bombardment. However, changes in the ultimate yield stress of the carbon reinforced epoxy composites correlate neither with weave direction nor fiber type. Unexpected developments were the discovery of new synergistic effects of the space environment in the interaction of atomic oxygen and copious amounts of contamination and in the induced luminescence of many materials. THE EFFECTS OF AN AGGRESSIVE ENVIRONMENT ON THE SUBCRITICAL CRACK GROWTH OF A CONTINUOUS-FIBER CERAMIC COMPOSITE
C. H. Henager, Jr. and R. H. Jones Jan. 1993 10 p Presented at the 16th Annual Conference on Composites, Materials, and Structures, Cocoa Beach, FL, 13-16 Jan. 1992
(Contract DE-AC06-76RL-01830)
(DE93-011690; PNL-SA-19958; CONF-920144-6) Avail: CASI HC A02/MF A01

Time-dependent crack growth measurements of ceramic composites in aggressive environments are being conducted on materials consisting of CVI SiC reinforced with Nicalon fibers (SiC/SiC(sub f)) having C and BN fiber-matrix interfaces. Crack velocities are determined as a function of applied stress intensity. Results have been obtained for crack velocity-stress intensity relationships in pure Ar and in Ar plus 2000 ppM O2 atmospheres at 1100 C. A 2D micromechanics model is used to represent the time-dependence of observed crack bridging events and is able to rationalize the observed phenomena. DOE

In cement-based materials, cement is usually employed to bind other materials together. Different interfaces are thus generated between various media in the resulted materials. It has been well recognized that the interfacial microstructure between cement binder and inclusions is of the greatest importance for the mechanical properties of the composite. Specifically, in fiber reinforced cementitious composites, the composite material properties are especially predominated by the fiber-cement interface due to its influence on the mechanical interactions between fibers and cement matrix. This report summarizes research investigations and findings of a study of the fiber-cement interfacial debond mode, namely strength-based or fracture-based debond modes and on an issue of interfacial bond property control. These studies have been done with the help of fiber pull-out experiments using an MTS digitally controlled load frame and micromechanical modeling, accompanied by environmental scanning electron microscopy. We expect that such investigations will provide physical insights into the break-down processes occurring at the interphase levels of fiber reinforced cementitious composites. The knowledge, in turn, many serve to achieve fiber reinforced cementitious composites with higher performance. DTIC

LOCALIZED AND DISTRIBUTED FIBER-OPTIC STRAIN SENSORS EMBEDDED IN COMPOSITE MATERIALS Thesis
Tomas Valis Sep. 1992 301 p Sponsored by Ontario Laser and Lightwave Research Centre; Natural Sciences and Engineering Research Council; and Inst. for Space and Terrestrial Science
(UTIAS-346; AD-B172623L) Copyright Avail: Issuing Activity

Fiber-optic sensors capable of being surface-adhered, or embedded within advanced composite materials to measure local strain are developed. Three types of strain sensors -- polarimeter, Michelson interferometer, and Fabry-Perot interferometer -- are built and tested in both uniaxial and rosette configurations. These are embedded in graphite/PEEK thermoplastic and Kevlar/epoxy thermoset composite laminates. Parameters that are experimentally determined include: response linearity, strain sensitivity, transverse-strain sensitivity, temperature cross-sensitivity, and maximum elongation. The fiber-optic strain rosettes demonstrated in situ strain-tensor measurement. Issues related to the compatibility and interaction of optical fibers with composite materials are addressed. A passive-quadrature phase-demodulation scheme for the Michelson interferometer is reported. The fiber-optic strain sensor with the most desirable properties is determined to be the Fabry-Perot interferometer. A technique for distributed strain-sensing based on counterpropagating waves coupled through backward stimulated-Raman-scattering is treated theoretically. Author (revised)

LIQUID COOLED HEAT SINK WITH THROUGH VIAS (LCHS) Interim Report, Dec. 1992 - May 1993
Charles W. Eichelberger and J. Patrick Kusior 31 May 1993 13 p
(Contract N00014-91-C-0219; ARPA Order 8021)
(AD-A266008) Avail: CASI HC A03/MF A01

This document presents the results of the Liquid Cooled Heat Sink with Through Vias (LCHS) Program. The goal of the program was to fabricate a structure with microchannels and through vias. The microchannels allow a heat dissipating liquid to flow through the structure while the vias provide an electrical pathway from the top of the structure to the bottom. A series of electrical and thermal tests were performed. The results of these tests have been interpreted. Recommendations to improve the current design were addressed. DTIC

ANALYTICAL MODELS FOR DESCRIBING THE MECHANICAL BEHAVIOR OF FIBER REINFORCED COMPOSITES Final Report, Jun. - Sep. 1992
James M. Whitney Sep. 1992 44 p
(Contract F33615-89-C-5609)
(AD-A265906; WL-TR-93-4060) Avail: CASI HC A03/MF A01

This report covers three topics in mechanics of advanced composites: effect of fiber cross-section on stiffness and strength of laminated composites; failure criteria for composites under combined loading; and stress analysis models for thick composites. In the area of fiber cross-sectional effect, micromechanics analysis addresses the effect of elliptical fibers on the stiffness and in-plane stress concentrations. Numerical results show that fiber cross-sectional geometry has only a modest influence on laminate elastic constants. The second topic addresses the interaction between longitudinal compression and transverse loading (tension and compression). Data obtained with a mini-sandwich beam are used to generate failure stresses. Classical lamination theory, including thermal residual stresses due to cure, is utilized for determining play stresses. Experimental results reveal little interaction between longitudinal compression and transverse stresses as long as the transverse load is below uniaxial transverse failure. Under the topic of thick composites, the effect of shear deformation and transverse normal stress on the cylindrical bending of laminated, anisotropic plates subjected to a uniform lateral load is investigated. Closed form solutions indicate that the effect of transverse normal stress on maximum deflection is small, even for relatively thick plates. DTIC

(AD-A265704; AFOSR-93-0394TR) Avail: CASI HC A04/MF A01

During the period of the grant we continued our modeling and analysis of the mechanical behavior of complex composite materials. Analytical and numerical modeling techniques of the influence of general composite laminate orientation on the ultrasonic behavior of anisotropic plates and substrates were developed. In the second phase piezoelectric effects were introduced into our modeling. In the final phase, the dynamic response of the layered composite to transient-loadings in the form of time-dependent source loads were studied. Complete documentation of the results of the first two phases were submitted to the AFOSR in the form of yearly reports. Since these reports contained completed items which also appeared in the literature as archival publications, we need not rereport them. Results for the recently completed works were also prepared for journal publication. Description of these works are included in detail. DTIC

PROTECTIVE COATINGS FOR HIGH-TEMPERATURE POLYMER MATRIX COMPOSITES
David R. Harding (Sverdrup Technology, Inc., Brook Park, OH.), James K. Sutter, and Demetrios S. Papadopoulos (Case Western Reserve Univ., Cleveland, OH.) Jul. 1993 16 p Proposed for presentation at the 25th International SAMPE Technical Conference, Philadelphia, PA, 26-28 Oct. 1993; sponsored by the Society for the Advancement of Material and Process Engineering
(RTOP 510-01-50)
(NASA-TM-106276; E-8013; NAS 1.15:106276) Avail: CASI HC A03/MF A01

Plasma-enhanced chemical vapor deposition was used to deposit silicon nitride on graphite-fiber-reinforced polyimide composites to protect against oxidation at elevated temperatures. The adhesion and integrity of the coating were evaluated by isothermal aging (371 C for 500 hr) and thermal cycling. The amorphous silicon nitride (a-SiN:H) coating could withstand stresses ranging from approximately 0.18 GPa (tensile) to -1.6 GPa (compressive) and provided a 30 to 80 percent reduction in oxidation-induced weight loss. The major factor influencing the effectiveness of a-SiN:H as a barrier coating against oxidation is the surface finish of the polymer composite. Author

PROPOSED FRAMEWORK FOR THERMOMECHANICAL LIFE MODELING OF METAL MATRIX COMPOSITES
Gary R. Halford, Bradley A. Lerch, and James F. Saltsman Washington Jul. 1993 15 p
(RTOP 505-63-52)
(NASA-TP-3320; E-7483; NAS 1.60:3320) Avail: CASI HC A03/MF A01

The framework of a mechanics of materials model is proposed for thermomechanical fatigue (TMF) life prediction of unidirectional, continuous-fiber metal matrix composites (MMC's). Axially loaded MMC test samples are analyzed as structural components whose fatigue lives are governed by local stress-strain conditions resulting from combined interactions of the matrix, interfacial layer, and fiber constituents. The metallic matrix is identified as the vehicle for tracking fatigue crack initiation and propagation. The proposed framework has three major elements. First, TMF flow and failure characteristics of in situ matrix material are approximated from tests of unreinforced matrix material, and matrix TMF life prediction equations are numerically calibrated. The macrocrack initiation fatigue life of the matrix material is divided into microcrack initiation and microcrack propagation phases. Second, the influencing factors created by the presence of fibers and interfaces are analyzed, characterized, and documented in equation form. Some of the influences act on the microcrack initiation portion of the matrix fatigue life, others on the microcrack propagation life, while some affect both. Influencing factors include coefficient of thermal expansion mismatch strains, residual (mean) stresses, multiaxial stress states, off-axis fibers, internal stress concentrations, multiple initiation sites, nonuniform fiber spacing, fiber debonding, interfacial layers and cracking, fractured fibers, fiber deflections of crack fronts, fiber bridging of matrix cracks, and internal oxidation along internal interfaces. Equations exist for some, but not all, of the currently identified influencing factors. The third element is the inclusion of overriding influences such as maximum tensile strain limits of brittle fibers that could cause local fractures and ensuing catastrophic failure of surrounding matrix material. Some experimental data exist for assessing the plausibility of the proposed framework. Author

ISOTHERMAL FATIGUE MECHANISMS IN Ti-BASED METAL MATRIX COMPOSITES Final Report
Bhaskar S. Majumdar and Golam M. Newaz Sep. 1993 62 p
(Contract NAS3-26494; RTOP 510-01-50)
(NASA-CR-191181; E-8086; NAS 1.26:191181) Avail: CASI HC A04/MF A01

Stress-controlled isothermal fatigue experiments were performed at room temperature (RT) and 548 C (in argon) on (0)8 SCS6/Ti 15-3 metal matrix composites (MMC's) with 15 and 41 volume percent SCS6 (SiC) fibers. The primary objectives were to evaluate the mechanical responses, and to obtain a clear understanding of the damage mechanisms leading to failure of the MMC's. The mechanical data indicated that strain ranges attained fairly constant values in the stress-controlled experiments at both RT and 538 C, and remained so for more than 85 percent of life. The fatigue data for MMC's with different volume fraction fibers showed that MMC life was controlled by the imposed strain range rather than the stress range. At RT, and at low and intermediate strain ranges, the dominant fatigue mechanism was matrix fatigue, and this was confirmed metallurgically from fractographic evidence as well as from observations of channel type dislocation structures in the matrix of fatigued MMC specimens. Reaction-zone cracks acted as important crack initiating sites at RT, with their role being to facilitate slip band formation and consequent matrix crack initiation through classical fatigue mechanisms. MMC life agreed with

matrix life at the lower strain ranges, but was smaller than matrix life at higher strain ranges. Unlike the case of monotonic deformation, debonding damage was another major damage mechanism during fatigue at RT, and it increased for higher strain ranges. At high strain ranges at RT, fractography and metallography showed an absence of matrix cracks, but long lengths of debonds in the outer layers of the SCS6 fibers. Such debonding and consequent rubbing during fatigue is believed to have caused fiber damage and their failure at high strain ranges. Thus, whereas life was matrix dominated at low and intermediate strain ranges, it was fiber dominated at high strain ranges. At 538 C, the mean stain constantly increased (ratchetting) with the number of cycles. At high strain ranges, such ratchetting led to overload failure of the fibers, and debonding of the type at RT was very small. At intermediate strain ranges, fractography showed large areas of matrix cracks. However, in spite of this matrix dominated mechanism, the MMC life at elevated temperatures was significantly less than the matrix fatigue life at all strain ranges. The reason for this difference is still unclear, although metallographic and fractographic evidences suggest that internal crack initiation sites at Mo-ribbons and reaction-zone cracks may have played a critical role, with the former tending to dominate.

AEROSOL SAMPLING MODELS SURVEY Final Report, Jun. - Dec. 1990
Dennis Metz and Paul Harvey Mar. 1993 151 p
(Contract DAAA15-87-D-0021)
(AD-A265903; ERDEC-CR-019) Avail: CASI HC A08/MF A02

The Obscuration Sciences Branch of the Physics Division, Research Directorate at the U.S. Army Chemical Research, Development, and Engineering Center, has undertaken a research project. This effort is aimed at identifying a comprehensive algorithm, computer program, or theory that might already exist and could be used to design aerosol sampling and transport systems. Initially, a literature survey was performed by the Obscuration Sciences Branch which began with several hundred potential articles and has been distilled to four candidate reports. This report evaluates the four candidate aerosol sampling models for self consistency and compares the numerical calculations resulting from four models. Finally a comparison of these model-derived results is made to the experimentally-derived results.

Moessbauer spectroscopy has been used over the past two decades to advance the study of europium compounds and alloys, primarily utilizing the 21.6-keV gamma ray emitted from beta decaying Sm-151. This isotope, which has a 87 year half-life, has been used in either a samarium fluoride (SmF3) or samarium oxide (Sm2O3) matrix. We now report a study involving, europium oxalate decahydrate (Eu2(C2O) (center dot) 10(H2O)), europium fluoride EuF3, and EuBe13 as absorbers at known thicknesses. Our data supports the view that Sm2(C2O4)(sub 3)(center dot) H2O will provide a better source matrix than either the fluoride or oxide due to the narrower linewidth and comparable 'f' factor to (Sm-151)F(sub 3). An object of this invention is a simple, cheap, selective and clean electrochemical removal of non-diamond carbon from a surface at below or above room temperature. Another object of this invention is to electrochemically pattern a substrate with non-diamond carbon with high resolution and relatively undamaged exposed surface. These and other objects of this invention are realized by a process which comprises disposing a surface with a non-diamond carbon layer in an electrolyte and subjecting the surface to sufficient electric field. The selective removal of non-diamond carbon is achieved by the addition of a mask on the non-diamond carbon layer. These and other objects of this invention are also realized by patterned diamond products made by the procedure disclosed herein. DTIC

Research during this year focused on the angular dependence of polarization of electrons backscattered from metallic surfaces, as a function of energy loss, using spin-polarized electron energy loss spectroscopy (SPEELS), and on dynamics of metastable He deexcitation at Xe-covered metallic surfaces using spin-polarized metastable deexcitation spectroscopy (SPMDS). In the SPEELS study, the data from Au, Ag, Mo, and Fe surfaces suggest that all inelastically scattered electrons underwent small-angle inelastic scattering either preceded or followed by large-angle elastic scattering that redirects the incident electron away from the target. The SPMDS study was extended from other gases to include rare gas adsorbates on Cu(100) and Au(100) surfaces; the spectra from the Xe-metal systems are unlike those from other systems and may provide new insights into metastable atoms. We have examined the stepwise-resonant free-photon-ionization spectrum of neutral zirconium atoms using three separately-tunable pulsed visible dye lasers. The ground-level (first-step) transitions were chosen on the basis of demonstrated Zr-91 selectivity. Lifetimes of even-parity levels around 36000/cm, measured with the delayed-photoionization technique, range from 10 to 100 ns. Direct ionization cross sections appear to be less than 10(exp -17) sq cm; newly-detected autoionizing levels give peak ionization cross sections (inferred from saturation fluences) up to 10(exp -15) sq cm. Portions of Rydberg series converging to the 315 and 763/cm levels of Zr(+) were identified. 'Clumps' of auto-ionizing levels are thought to be due to Rydberg-valence mixing. DOE

(Contract DE-AC07-76ID-01570)
(DE93-012185; EGG-WTD-10507) Avail: CASI HC A03/MF A01

The direct detection of tributyl phosphate (TBP) on rocks using molecular beam surface analysis (MBSA or in situ secondary ion mass spectrometry (SIMS)) is demonstrated. Quantities as low as 250 ng were detected on basalt and sandstone with little or no sample preparation. Detection of TBP on soil has proven to be more problematic and requires further study. Ethylene- diamine- tetra- acetic acid (EDTA) is more difficult to detect because it is very reactive with surfaces of interest. Nevertheless, it is possible to detect EDTA if the acidity of the surface is controlled. The detection of EDTA-metal complexes is currently an open question, but evidence is presented for the detection of ions arising from a EDTA-lead complex. Carboxylic acids (i.e., citric, ascorbic, malic, succinic, malonic, and oxalic) give characteristic SIM spectra, but their detection on sample surfaces awaits evaluation. DOE

A THEORY OF MEMBRANE ABSORBERS
M. J. Fisher Mar. 1993 33 p
(ISVR-TR-217) Copyright Avail: Issuing Activity (Institute of Sound and Vibration Research, University of Southampton, Southampton SO9 5NH, England)

The use of membrane absorbers, traditionally considered as a combination of a baffle resonator and Helmholtz resonator, are finding applications in an increasingly wide field of industrial noise control applications. Previous theoretical work in this area appears to have assumed that each resonator acts independently of the other; each controlling the absorption in its own frequency range. We consider them as two coupled oscillators, the coupling arising through the fluctuation of pressure in the absorber cavity which drives both the membrane and air through the Helmholtz resonator exit. The coupling is demonstrated to yeild a number of important effects which should be included in a rational design procedure for membrane absorbers. Author (revised)

PHASE EQUILIBRIA AND VOLUMETRIC PROPERTIES FOR THE SYSTEM NaCl-CaCl2-H2O Ph.D. Thesis
Charles Steger Oakes 1993 119 p
(Contracts DE-FG05-89ER-14065; DE-AC05-84OR-21400)
(DE93-013590; DOE/ER-14065/T1) Avail: CASI HC A06/MF A02

Low temperature phase relations in the ice-stable field of the system NaCl-CaCl2-H2O were determined under 1 atm. total pressure along the NaCl-H2O and CaCl2-H2O binaries and along five pseudobinaries with constant NaCl/(NaCl + CaCl2) weight ratios. The results are in excellent agreement with published data along the NaCl-H2O binary but show large discrepancies when compared to previous determinations of the ice liquidus alone, the CaCl2-H2O binary and in the NaCl-CaCl2-H2O ternary. At moderate to high salinities, isotherms cross the ice sub-field at lower total salt concentrations than previously reported. In addition, NaCl(NaCl + CaCl2) weight ratios estimated from hydrohalite- and ice-melting temperatures may be low by as much as 15%. Relative densities were measured for NaCl(aq) and CaCl2(aq) solutions to 250 C and 400 bars and over the range of ionic strengths 0.2-5.5 and 0.2-19.2 mol (center dot)/kg, respectively. The results span the pressure and temperature of earlier volumetric studies and extend to higher molalities than reported previously. The relative densities have been fitted as apparent molar volumes (V(sub phi)) using the Pitzer ion-interaction treatment, with appropriate expressions chosen for the temperature- and pressure-dependence of the virial coefficients of the model. The results presented for NaCl(aq) are in good agreement with published results to 250 C. The results presented for CaCl2(aq) are in good agreement with published values to approximately 125 C. DOE

KIVA-3: A KIVA PROGRAM WITH BLOCK-STRUCTURED MESH FOR COMPLEX GEOMETRIES
A. A. Amsden Mar. 1993 97 p
(Contract W-7405-eng-36)
(DE93-011986; LA-12503-MS) Avail: CASI HC A05/MF A02

This report describes the KIVA-3 computer program for numerical calculation of transient, two- and three-dimensional chemically reactive fluid flows with sprays. KIVA-3 is an extension of the earlier KIVA-2, uses the same numerical solution procedure, and solves the same set of equations. The full generality of KIVA-II has been retained; thus KIVA-3 is applicable to laminar or turbulent flows, subsonic or supersonic flows, and single-phase or dispersed two-phase flows. KIVA-3 differs from KIVA-2 in that it uses a block-structured mesh with connectivity defined through indirect addressing. The departure from a single rectangular structure in (i,j,k) logical space allows complex geometries to be modeled with significantly greater efficiency than was previously possible because large regions of deactivated cells are no longer necessary. Cell-face boundary conditions permit greater flexibility and simplification in the application of boundary conditions. This report discusses those features of KIVA-3 that differ from KIVA-2, the input required from a mesh generation preprocessor, and the output provided to a graphics postprocessor. Basic pre- and post-processors are included in the KIVA-3 package, and are also described. DOE

SIZE DEPENDENCE OF CHEMICAL REACTIVITY OF GASEOUS METAL CLUSTERS: A NEW MECHANISTIC PROBE
M. A. El-Sayed 17 May 1993 17 p
(Contract N00014-89-J-1350)
(AD-A264690; TR-75) Avail: CASI HC A03/MF A01

The determination of the mechanisms of chemical reactions leading to the formation of different types of materials is one of the principal occupations of many chemists today. To accomplish this, the dependence of the observed transformation is studied as a function of a number of intensive variables such as temperature, pressure, concentration of reactants as well as the Hydrogen ion concentration of the solution. In this account, we summarize recent studies in which the observed changes of the chemical reactivity of gaseous niobium clusters with size was used as a new degree of freedom that assists in deducing the mechanism of the chemical reactions studied. X RAY ABSORPTION SPECTROSCOPY OF ELECTROCHEMICALLY GENERATED SPECIES
William R. Heineman and Richard C. Elder 19 Feb. 1993 22 p
(Grant AF-AFOSR-0089-88)
(AD-A264749; AFOSR-93-0209TR) Avail: CASI HC A03/MF A01

X-ray absorption fine structure (EXAFS) spectroscopy has been combined with electrochemistry to enable the measurement of coordination numbers, donor atom types, and bond lengths of metal ions in multiple oxidation states which are generated electrochemically. We have demonstrated the applicability of this technique to study the redox coordination chemistry of metal ions in aqueous and nonaqueous solvents, ionically conducting polymer films, electroactive films on conducting metals, and electrically conducting polymers. Our objectives were to conduct research in the following areas: (1) electrostatic cross-linking of ionic polymer films and their effects on the structures of charged coordination compounds immobilized in the film; (2) cation charge transport and its effects on the structures of electroactive films such as Prussian blue deposited on electrodes; (3) metal ions incorporated in electrically conducting polymers; (4) development of a flow cell which enables EXAFS spectroelectrochemistry to be performed in a controlled atmosphere environment; (5) structure determination for metals and intermetallic compounds in mercury solvent; and (6) evaluation of spectroelectrochemical nernstian plots. CHARACTERIZATION OF GAS-AEROSOL INTERACTION KINETICS USING MORPHOLOGY DEPENDENT STIMULATED RAMAN SCATTERING
P. M. Aker 30 Jan. 1993 20 p
(Contract DE-FG02-92ER-61480)
(DE93-012324; DOE/ER-61480/1) Avail: CASI HC A03/MF A01

This study is aimed at characterizing the influence of aerosol surface structure on the kinetics of gas-aerosol interactions. Changes in gas phase chemical reaction rates as a function of exposure to a specific aerosol are measured with aerosols having different surface properties due to the composition and/or temperature of the material making up the aerosol. The kinetic data generated can be used directly in atmospheric modeling calculations. The surface structure of the aerosol is determined using morphology-dependent enhancement of simulated Raman scattering (MDSRS). Detailed dynamics of gas-aerosol interactions can be obtained by correlating the change in the reaction rate with change in surface structure and by monitoring the change in aerosol surface structure during, the course of the reaction. This dynamics information can be used to generate kinetic data for systems which are similar in nature to those studied, but are not amenable to laboratory investigation. We show here that increased MDSRS sensitivity is achieved by using an excitation laser source that has a narrow linewidth and we have been able to detect sulfate anion concentrations much lower than previously reported. We have shown that the linewidth of the MDSRS mode excited in a droplet is limited by the laser linewidth. This result suggests that MDSRS signal size should be independent of droplet size, and preliminary experiments confirm this hypothesis. DOE

A MODEL OF ELEMENTARY CHEMISTRY AND FLUID MECHANICS IN THE COMBUSTION OF HYDROGEN ON PLATINUM SURFACES
J. Warnatz (Stuttgart Univ., Germany.), M. D. Allendorf, R. J. Kee, and M. E. Coltrin Apr. 1993 21 p
(Contract DE-AC04-76DP-00789)
(DE93-012767; SAND-93-8228) Avail: CASI HC A03/MF A01

Using computational methods, we consider the catalyzed combustion of lean hydrogen-oxygen mixtures in a stagnation flow over a platinum surface and in a flat-plate boundary layer. The analysis includes elementary chemistry in the gas phase as well as on the surface. The stagnation flow is modeled using a similarity transformation that leads to a one-dimensional boundary-value problem, whereas the flat-plate boundary layer is modeled by use of the boundary-layer assumption. Predictions of each model are compared with experimental measurements of catalytic ignition and combustion of hydrogen-oxygen mixtures at low pressure (100 mTorr) and OH concentration profiles in catalytically supported combustion at atmospheric pressure. The paper proposes reaction mechanisms and interprets the catalytic behavior in terms of the chemistry models. DOE

THE SOLUBILITY OF EPSILON-CL-20 IN SELECTED MATERIALS
E. vonHoltz, D. Ornellas, M. F. Foltz, and J. E. Clarkson Aug. 1992 31 p Presented at the Energetic Materials for Munitions Conference, China Lake, CA, 22-24 Sep. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-009304; UCRL-JC-111005; CONF-9209326-1) Avail: CASI HC A03 (US Sales Only)

Solubility of the epsilon polymorph of CL-20 was determined in thirteen liquids over temperature range ambient to 74C using high performance liquid chromatography. The experiments included epsilon-CL-20 produced by two different synthesis routes; one lot contained a higher level of polymorphic impurity, the other lot contained a higher level of non-CL-20 impurity. In general, the epsilon-CL-20 was found to be highly soluble in the solvents with carbonyl groups, and relatively insoluble in hydrocarbons and materials containing ether linkages. The amount of phase conversion to gamma-CL-20 which occurred during the solubility testing was measured using FRIR, and ranged from essentially zero to approximately 10%

conversion. It appears that the presence of Beta-CL-20 in the virgin epsilon-CL-20 lots will affect the amount of gamma-phase present in the final residue. DOE

N94-11622# Oak Ridge National Lab., TN.
THERMOGRAPHIC PROPERTIES OF EIGHT BLUE-EMITTING PHOSPHORS
D. M. Cunningham, S. W. Allison, and D. B. Smith Jan. 1993 47 p
(Contract DE-AC05-84OR-21400)
(DE93-011459; ORNL/ATD-70) Avail: CASI HC A03/MF A01

We examined the effect of temperature on the light emission and absorption properties of eight phosphorescent compounds. The phosphors are commercially produced powders that emit mainly in the blue region when illuminated with ultraviolet light (220 to 400 nm). Excitation and emission spectra taken over the temperature range of 20 to 350 C are presented for these phosphors. Data from the spectra indicate a strong temperature dependence over this temperature range. Maximum relative intensity changed as a function of temperature in every phosphor examined. In some samples, spectral band shifts and bandwidths also changed with temperature. Of these phosphors, BaMg2Al16O27:Eu and (Ba3PO4)(sub 2):Eu are candidates for higher-temperature studies. DOE

ALUMINUM-PHOSPHORUS CHEMISTRY: PREPARATION AND STRUCTURAL CHARACTERIZATION OF (Et2AlP(SiMe3)2)2, Et(Cl)2Al(DOT)P(SiMe3)3, AND i-Bu2(Cl)Al(DOT)P(SiMe3)3
Richard L. Wells, Andrew T. McPhail, and Mark F. Self 24 Mar. 1993 31 p
(Contract N00014-89-J-1545)
(AD-A265268; DU/DC/TR-35) Avail: CASI HC A03/MF A01

Reactions of R2AlCl (R = Et, i-Bu) and EtAlCl2 with P(SiMe3)3 and LiP(SiMe3)2 were studied to investigate the potential use of dehalosilylation and lithium chloride elimination reactions for the preparation of compounds containing either Al-P-Al-P or Al-P-Al-Cl core rings. The dimeric compound Et2AlP(SiMe3)22 (1) was isolated from the 1:1 reaction of Et2AlCl and LiP(S iMe3)2 at -78 C, as a result of LiCl elimination. The 1:1 reaction of EtAlCl2 and P(SiMe3)3 yields Et(Cl)2Al(dot)P(SiMe3)3 (2). Interestingly, a similar reaction between Et2AlCl and P(SiMe3)3 in a 2:1 mole ratio also affords (2), in moderate yield, suggesting a rearrangement of the original aluminum alkylhalide. However, when Et2AlCl was reacted with P(SiMe3)3 in a 1:1 mole ratio, the expected adduct Et2(Cl)Al(dot)P (SiMe3)3 (3) results. Unlike the Et2AlCl reaction, the analogous 2:1 mole reaction of i-Bu2AlCl and P(SiMe3)3 forms the mono-chloro adduct, i-Bu2AlCl(dot)P(SiMe3)3 (4), rather than a rearrangement product. DTIC

DIELECTRIC BREAKDOWN AND ITS INFLUENCE ON IGNITION Final Report
M. M. Chaudhri, F. A. Al-Ramadhan, and I. U. Haq Mar. 1993 74 p
(Contract MOD-D/ER1/9/4/2029/RARDE)
(AD-A264925) Avail: CASI HC A04/MF A01

Electrical conduction, dielectric breakdown, and the consequent ignition of small pellets, 0.2 to 5 mm in thickness and 5 to 7 mm in diameter, of MTV compositions SR886B, SR886E, and SR886E have been investigated. The investigations were made using d.c fields and high-speed photography at framing rates of up to one million frames per second was employed to follow the breakdown and ignition behavior. It was found that under suitable conditions, the dielectric breakdown of the samples led to their ignition and the delay time between the breakdown and ignition could be as small as 20-25 microseconds. Furthermore, a special circuit was designed and constructed for determining the minimum ignition energies of samples of different thicknesses. It was found that for samples of thickness of approximately 0.2 mm, the minimum electrostatic energy which could cause ignition was as low as approximately 1 mJ. Moreover, the minimum ignition energy was found to increase with the sample thickness. A model, based on our previous model for the electrical ignition of silver azide, has been proposed. According to this, the dielectric breakdown leads to the formation of high conductivity filaments in which Joule heating-results in the formation of high temperature hot spots. Ignition initiates at these hot spots. An essential feature of this model is that the dielectric breakdown is a prerequisite for electrical ignition. DTIC

Electrochemical studies are carried out in three main areas. Phthalocyanine electrochemistry: emphasis is placed on the chemistry of phthalocyanine modified electrodes for the study of electrocatalytic processes ultimately leading to chemical sensors. These studies include polymeric phthalocyanine conductive species. We also seek a comprehensive understanding of phthalocyanine electrochemistry to benefit all phthalocyanine redox applications. This work is extended to include Langmuir Blodgett (LB) surface (monolayer) phthalocyanine films with spectroelectrochemical studies being undertaken in situ on the trough surface. Redox active ligands and electronic structure: A broad range of chemical techniques (uv/vis/FTIR/resonance Raman/PES/X-ray/ Electrochemistry/solvatochromism/ ab initio calcs, are brought into play to understand the electronic structure, spectroscopy and electrochemistry of ruthenium (mainly) complexes of quinonoid ligands (including derivatives such as quinonediimines) where oxidation states are non-integral. In situ LB electrochemistry: studies of the interactions of surface films with subphase redox species, in situ, in an LB trough. This is exploratory work aimed at developing methods for creating arrays of molecules and studying them through electronic spectra and electrochemistry - towards nanotechnology. DTIC

TANDEM MASS SPECTROMETRIC ANALYSIS OF PHOSPHATE ESTERS
Paul A. DAgostino and Lionel R. Provost Mar. 1993 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265483; DRES-SR-581) Avail: CASI HC A03

A homologous series of phosphate esters (trimethyl phosphate, triethyl phosphate, tripropyl phosphate, and tributyl phosphate), which are often employed as chemical simulants for chemical warfare agents, were characterized by tandem mass spectrometry under EI conditions. The daughter spectra for the principal EI ions of each phosphate ester were acquired by stepping the collisional activated dissociation cell energy from 1 eV to 100 eV (laboratory scale) in 1 eV increments with residual air and argon target gases. A standardized MS/MS setup procedure was established and the reproducibility of daughter scanning over the long and short term was evaluated. The sensitivity of capillary column GC-MS/MS was excellent and approximated that achieved during full scanning capillary column GC-MS analysis under EI conditions. Author (DTIC)

VIBRATIONAL OVERTONE ACTIVATION OF METHYLCYCLOPROPENE

Geoff Snavely, Salah Hassoon, and D. L. Snavely 27 May 1993 10 p
(Contract N00014-83-K-4130)
(AD-A265588; TR-12) Avail: CASI HC A02/MF A01

The photoisomerization of 1-methylcyclopropene (MCPene) was studied at specific internal energies accessed by laser vibrational overtone activation. The vibrational overtone spectrum of the 6-0 and 5-0 CH stretches were observed for our synthesized mixture of 75% MCPene and 25% methylenecyclopropane (MCPane). The overtone spectrum of neat MCPane was determined in the spectral regions. The transition wavenumbers were compared to the previously known members of the vinyl, methylenic, and methyl vibrational progressions. Product yields from activation through the 5-0 vinyl and methyl CH stretches were determined using gas chromotography. Product ratios of 1,3-butadiene to 2-butyne were measured as a function of pressure and compared to the RRKM predicted yields. After careful measurements we conclude that at these photolysis energies methylcyclopropene does not produce methylenecyclopropane. DTIC

MAPPING CLOSURES FOR TURBULENT COMBUSTION Annual Report, 15 Feb. 1992 - 14 Feb. 1993

Stephen B. Pope 31 Mar. 1993 11 p
(Grant AF-AFOSR-0184-91)
(AD-A265671; AFOSR-93-0380TR) Avail: CASI HC A03/MF A01

The overall objective of the research program is to develop and test an improved model for the process of molecular diffusion in turbulent reactive flows. In application to turbulent combustion, a major shortcoming of existing models is that they are non-local in composition. A model based on the construction of a Euclidean minimum spanning tree (EMST) has been developed. This model is inspired by the mapping closure and reduces to it in the case of a single composition. In general, the model is asymptotically local and hence, overcomes a major flaw in previous models. Additionally, studies have been made of stochastic Lagrangian models for turbulent reactive flows, and an exact expression has been obtained for the probability density function of temperature (or other random quantities) in statistically stationary turbulence. DTIC

THEORIES OF TURBULENT COMBUSTION IN HIGH SPEED FLOWS Annual Report, Apr. 1992 - Apr. 1993

P. A. Libby and F. A. Williams 9 Apr. 1993 7 p
(Contract F49620-92-J-0184)
(AD-A265735; AFOSR-93-0382TR) Avail: CASI HC A02/MF A01

This research involves theoretical studies of the chemical and fluid mechanical phenomena which make turbulent combustion in high-speed flows different from such combustion in low-speed flows. Finite-rate chemistry plays a significant role in high-speed flows because of the small ratios of flow times to chemical times. The study addresses ignition and extinction phenomena in the nonpremixed turbulent combustion of hydrogen-air systems by both numerical and asymptotic methods. Attention also is paid to the effects of compressibility in high-speed turbulent combustion, with consideration given to interdispersal configurations of shocklets and flamelets. Efforts are made to provide a firmer foundation for the modeling of high-speed turbulent reacting flows, to aid in the development of a formulation which gives results that can be compared with experiments, and on turbulent combustion. DTIC

METHANOL PAN FIRES IN AN ENCLOSED SPACE: EFFECT OF PRESSURE AND OXYGEN CONCENTRATION

J. L. Bailey, F. W. Williams, and P. A. Tatem 24 Mar. 1993 55 p
(AD-A266108; NRL/MR/6180-93-7310) Avail: CASI HC A04/MF A01

A series of fire tests was conducted in FIRE I, a large-scale pressurizable fire test chamber, to investigate the effect of pressure and oxygen concentration on methanol pan fires. As the oxygen concentration decreased from 21 vol-% to 13.5 vol-% throughout the experiments, the mass loss rate linearly decreased from 10 kg/hr to 6.6 kg/hr. Below 13.5 vol-% oxygen concentration, the mass loss rate rapidly declined. The fire self-extinguished when the oxygen concentration level approached 12 vol-%. An increase in initial chamber pressure from 14.7 psi to 23.9 psi (at 21 vol-% initial oxygen concentration) increased the burning rate by 34%. Experiments are planned at combinations of higher than ambient pressures and lower than ambient oxygen concentrations in order to quantify the combined effect of these variables on the mass loss rate of methanol. Experiments are also planned to determine the effect of pressure and oxygen concentration on the burning rates of other fuels. DTIC

NONLINEAR OPTICAL SPECTROSCOPY OF Ag(111) IN ELECTROLYTE AND IN VACUUM Technical Report No. 2, May 1992 - May 1993

R. Bradley, R. Georgiadis, S. D. Kevan, and G. L. Richmond 27 May 1993 43 p
(Contract N00014-89-J-1261)
(AD-A265622) Avail: CASI HC A03/MF A01

In this paper, we investigate the electronic structure of a metal surface in the presence of aqueous electrolyte and an applied potential by optical second harmonic generation (SHG). We have obtained the detailed wavelength dependence (lambda(sub SH) = 300-350 nm) of the SH response from Ag(111) in both an aqueous electrolyte and in ultrahigh vacuum (UHV) and find that, when the Ag(111) electrode is biased at the potential of zero charge (PZC), the SH response is strongly correlated with the SH response in UHV. For the surface in both environments there is a sharp peak near 3.82 eV. Possible contributing factors to this peak are discussed. In the electrochemical environment, the effect of applied potential on the SH response at longer wavelengths, (nonresonant regime), is consistent both with previous observations at fixed frequencies and predictions of the surface charge density (SCD) model. At resonant wavelengths, there is a dramatic deviation from behavior predicted by the SCD model, a result consistent with previous experiments at discrete wavelengths. DTIC

THE ADSORPTION AND SURFACE REACTION OF SiCl4 ON Si(100)-(2X1) Technical Report No. 57

Q. Geo, Z. Dohnalek, C. C. Cheng, W. J. Choyke, and J. T. Yates, Jr. 26 May 1993 30 p
(Contract N00014-82-0280)
(AD-A266124) Avail: CASI HC A03/MF A01

The adsorption and surface reaction of SiCl4 on Si(100)-(2x1) have been investigated in the temperature range of 100K-1000K. Adsorption of monolayer SiCl4 and multilayer SiCl4 are observed by temperature programmed desorption (TPD), high resolution electron energy loss spectroscopy (HREELS), and electron stimulated desorption ion angular distribution (ESDIAD). Upon heating to approx. 200K and above, Si-Cl bond scission in adsorbed SiCl4 occurs, depositing SiCl(x) species. Heating to 673K leaves the surface with only silicon monochloride species, SiCl(a), exhibiting Si-Cl stretching mode, vSiCl, at approx. 560 cm/cm, and a Cl(+) ESDIAD pattern indicative of inclined Si-Cl bond directions from Cl adsorbed on Si2 dimer sites. Silicon substrate etching occurs above 800K producing SiCl2(g) as the desorption product. Author (DTIC)

BIBLIOGRAPHY ON HOT ISOSTATIC PRESSING (HIP) TECHNOLOGY
B. F. Gilp, P. D. Desai, J. F. Radavich, and C. Y. Ho Nov. 1992 325 p
(Contract DLA900-90-D-0305)
(AD-A265668; MIAC-1) Avail: CASI HC A14/MF A03

This report contains an annotated bibliography of 950 documents on the Hot Isostatic Pressing (HIP) Technology dealing with metals, alloys, and intermetallic compounds and covers over 450 materials. Documents published from 1966 to early 1992 are covered. Bibliographic information reported here are divided into three broad categories. The first category includes an annotated bibliography dealing with HIP technology as applied to powder metallurgy. The second category deals with casting and the third deals with miscellaneous materials which either are not properly identified or have a limited number of bibliographic citations. Within each category, bibliographic information is organized according to major alloy groups, e.g., aluminum alloys, beryllium alloys, cobalt alloys, etc., followed by bibliographies for miscellaneous alloys which are alloys either not properly identified or not having enough data to warrant a separate category. Each alloy group is further subdivided into individual commercial alloys, e.g., aluminum alloys AA 2024, AA 7075, AA 7090, etc., followed by miscellaneous aluminum alloys. DTIC

FRACTOGRAPHY HANDBOOK OF SPACEFLIGHT METALS
Rebecca J. Derro Washington Jun. 1993 126 p
(NASA-RP-1291; Rept-93B00019; NAS 1.61:1291) Avail: CASI HC A07/MF A02

This handbook was produced with the intention of providing failure analysts who work with space flight metals a reference of scanning electron microscope (SEM) fractographs of fracture surfaces produced under known condition. The metals and the fracture conditions were chosen to simulate situations that are encountered in spaceflight applications. This includes tensile overload at both room temperature and liquid nitrogen temperature, and fatigue at room temperature. Author

MONTE CARLO SIMULATIONS OF PHASE TRANSFORMATIONS IN Fe-Cr ALLOYS
L. Reinhard and P. E. A. Turchi 1 Dec. 1992 8 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract W-7405-eng-48)
(DE93-013847; UCRL-JC-111004; CONF-921101-117) Avail: CASI HC A02/MF A01

Phase stability properties of bcc based Fe-Cr alloys are examined in the framework of the first-principles KKR-CPA-GPM formalism and Monte Carlo simulations. For Fe-rich alloys, ordered configurations are found stable with respect to the random state of the alloy, but unstable with respect to the pure Fe and Cr metals. Results are compared with the ones obtained by using energy parameters extracted from experimental diffuse scattering data. DOE

EFFECT OF SURFACE CLEANLINESS OF BEARING STEEL ON ADHESIVE STRENGTH AND TRIBOLOGICAL PROPERTIES OF SPUTTER-DEPOSITED GOLD FILMS [KINMAKU NO FUCHAKU KYOUDO OYOBI JUNKATSU TOKUSEI NI OYOBOSU JIKUUKEKOU KIBAN HYOUMEN SEIJOUDO NO EIKYOU]
Makoto Nishimura and Akihiko Matsui Apr. 1992 22 p In JAPANESE
(DE93-767974; NAL-TR-1148; JTN-93-80431) Avail: CASI HC A03/MF A01

The tribological responses of gold films sputtered on bearing steel and the effects of surface cleanliness on the film's adhesive strength were studied using X-ray Photoelectron Spectroscopy (XPS). To eliminate air contamination, a sputtering apparatus was built in the spectrometer and the gold film was directly deposited on characterized steel surfaces. The adhesion strength was evaluated by an epoxy resin adhesion strength measuring and also by a sliding friction test method conducted in nitrogen using a pin-on-disc type tester. Results showed the adhesive strength measuring method can effectively determine the existence of several tenth-layer to a monolayer of anti-rust agent. A sliding friction test indicated that the film's wear life was sensitive to the presence of oxygen and carbon following anti-rust agent removal by ion-bombardment. In addition, a monolayer of anti-rust agent, remaining on the surface after solvent cleaning, was found to lower the friction coefficient in the first ten repeated traverses under the test conditions employed. APPLICATION OF POWDER METALLURGY TECHNIQUES TO PRODUCE IMPROVED BEARING ELEMENTS FOR LIQUID ROCKET ENGINES Final Report, Feb. 1982 - Aug. 1992
D. J. Moracz, R. J. Shipley, V. S. Moxson, R. J. Killman, and H. E. Munson Aug. 1992 115 p
(Contract NAS8-34763)
(NASA-CR-193731; NAS 1.26:193731; EER-1041) Avail: CASI HC A06/MF A02

The objective was to apply powder metallurgy techniques for the production of improved bearing elements, specifically balls and races, for advanced cryogenic turbopump bearings. The materials and fabrication techniques evaluated were judged on the basis of their ability to improve fatigue life, wear resistance, and corrosion resistance of Space Shuttle Main Engine (SSME) propellant bearings over the currently used 440C. An extensive list of candidate bearing alloys in five different categories was considered: tool/die steels, through hardened stainless steels, cobalt-base alloys, and gear steels. Testing of alloys for final consideration included hardness, rolling contact fatigue, cross cylinder wear, elevated temperature wear, room and cryogenic fracture toughness, stress corrosion cracking, and five-ball (rolling-sliding element) testing. Results of the program indicated two alloys that showed promise for improved bearing elements. These alloys were MRC-2001 and X-405. 57mm bearings were fabricated from the MRC-2001 alloy for further actual hardware rig testing by NASA-MSFC. Author (revised)

ON PROBLEM ABOUT NATURE OF PORTEVIN-LE CHATELIER EFFECT IN IRRADIATED ALUMINIUM ALLOYS [K VOPROSU O PRIRODE EHFFEKTA PORTEVENA-LE-SHATEL'E V OBLUCHENNYKH ALYUMINIEVYKH SPLAVAKH]
V. N. Drobyazin, S. P. Polovneva, Y. S. Podzirej, G. A. Soldatenko, and V. G. Vorobev 1991 15 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617200; KIYal-91-14) Avail: CASI HC A03 (US Sales Only)

The influence of hardening return, deformation ageing, and gamma-irradiation on the Portevin-le-Chatelier effect in aluminum alloys (D16, D95, AK4, and AK6) was investigated. It was shown that the hardening temperature slightly influences on the discontinuous current nature, whereas the temperature and ageing on return causes the considerable changes of Portevin-le-Chatelier. It was shown that the irradiation of gamma-quantum low doses causes the Portevin-le-Chatelier effect in natural-aged state of alloy and disappearance of its effect during the subsequent ageing or during the irradiation with high doses. PARTICLE ATTRACTION EFFECTS ON THE CENTRIFUGAL CASTING AND EXTRUSION OF ALUMINA
C. H. Schilling, L. Bergstroem (Stockholm Univ., Sweden.), H. L. Ker (Princeton Univ., NJ.), and I. A. Aksay (Princeton Univ., NJ.) 1993 17 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract W-7405-eng-82)
(DE93-011559; IS-M-744; CONF-930438-4) Avail: CASI HC A03/MF A01

Interparticle attraction forces were empirically related to the centrifugal casting and extrusion behavior of flocculated alumina suspensions. Attractive forces were altered by two approaches: salt flocculation, which entails regulating the electrical double-layer thickness through electrolyte additions; and screening of van der Waals attraction by steric interactions of surface-adsorbed fatty acids. Specimens produced by both methods exhibited a shift from high to low compressibility at a critical maximum density that increased with decreasing interparticle attraction. Gradients in packing density during centrifugal casting were alleviated using both methods as long as spatial variations of the effective stress were within the low-compressibility range. We hypothesized that the reduced interparticle attraction in both methods may also raise the threshold packing density at which ductile-to-brittle transitions occur during plastic shear. Specimens prepared with oleic acid adlayers were highly plastic and easily extrudable at solids contents of up to 59 vol%, although salt-flocculated samples at 55 vol% density extruded at creeping flow rates that were insensitive to the applied pressure. Results suggested that particle rearrangement during shear is a rate-limiting process, with an average relaxation time that is lowered by reducing interparticle attraction. DOE

DAMPING MEASUREMENTS FOR ULTRA-HIGH CARBON STEEL/BRASS LAMINATES
B. P. Bonner, D. R. Lesuer, C. K. Syn, A. E. Brown, and O. D. Sherby (Stanford Univ., CA.) 26 Oct. 1992 7 p Presented at the Minerals, Metals, and Materials Society/American Society for Metals Materials Week 1992, Chicago, IL, 2-5 Nov. 1992
(Contract W-7405-eng-48)
(DE93-011886; UCRL-JC-110334; CONF-9211117-6) Avail: CASI HC A02/MF A01

Damping measurements were made at high and low frequencies to investigate laminated metal composites (LMC's) consisting of ultrahigh carbon steel and brass for use in applications that require high damping capacity while maintaining strength and toughness. Properties of such laminates can be tailored through the selection of the component materials, volume percentage of the materials, layer thickness, interface strength, and microstructural control. Damping was measured in the ultrasonic range (2.25 MHz) with pulse-echo torsional oscillator from 2 to 40 Hz in shear strain range 10(exp -7) to 10(exp -6). Results at low frequencies indicate that Q(sub s)(exp -1) is 2 to 3 times higher than that of the highest damping component (brass). Damping is also independent of the layer orientation. Ultrasonic attenuation is much larger than for the component materials, with insertion losses approximately 100 dB/m greater than either component. Microstructure (metallography, SEM) and correlations between laminate structure and damping behavior are discussed. DOE

A HISTORY OF TUNGSTEN- AND MOLYBDENUM-BASE ALLOYS

R. L. Heestand 1993 9 p Presented at the Annual Meeting of The Metallurgical Society, Denver, CO, 21-25 Feb. 1993
(Contract DE-AC05-84OR-21400)
(DE93-010283; CONF-930202-8) Avail: CASI HC A02/MF A01

The development of tungsten and molybdenum alloys was initiated in the early 1900s in search of a better electric lamp filament with tantalum, tungsten, rhenium, and osmium being the prime candidates. The efforts required for accomplishment of the task led to refining oxides to high purity, reduction of the oxides to metal powders, forming green product forms by extrusion or pressing, and finally sintering by electric furnace and self-heating by direct current almost to the melting point. The technology required for producing lamp filaments led to the development of the powder metallurgy field and early research on high-melting-temperature metals. During the period 1909 through 1959, most of the tungsten-molybdenum, high-melting-temperature element alloys were developed and produced in almost any product form required. DOE

PRODUCTION OF REACTIVE SINTERED NICKEL ALUMINIDE
R. M. Cooper 1993 8 p
(Contract DE-FG01-91CE-15492)
(DE93-014434; DOE/CE-15492/T4) Avail: CASI HC A02/MF A01

Our efforts over the past 3 months were directed at increasing manufacturing capacity (ball milling) and improving product quality. Orders for the powder have increased, mainly for plasma spray powders. NiAl is an excellent coat between a metal and a ceramic, and its use, instead of cobalt, should extend operating range for carbide tools. The feather phase in the sintered Ni3Al was identified to be a Ni-rich phase nucleated on the grain boundaries with 10 wt % Al composition. The ductile to brittle temperature of powder extruded NiAl was found to be between 500 and 600 C and shows a 50% elongation at 600 C. DOE

PROCESSING, PROPERTIES, AND WEAR RESISTANCE OF ALUMINIDES
R. N. Wright, B. H. Rabin, and J. K. Wright Mar. 1993 42 p
(Contract DE-AC07-76ID-01570)
(DE93-012186; EGG-MS-10441) Avail: CASI HC A03/MF A01

Fully dense alloys based on Fe3Al were produced by reaction synthesis from low cost elemental powders using hot pressing, hot isostatic pressing, or the Ceracon process. The reaction proceeds by outward spreading of a transient liquid phase from the initial aluminum particle site and precipitation of the compound phase from the liquid. Combustion synthesized material has a very fine grain size that is resistant to coarsening at high temperature because of a high density of fine oxides from the prior particle boundaries. The fine grain size results in approximately twice the yield strength in the reaction synthesized material compared to hot extruded pre-alloyed powder. Combustion synthesis has also been successfully applied to joining Fe3Al and to forming coatings on carbon steel substrates. Combustion synthesis has been shown to be viable for fabricating trialuminides from elemental powder compacts. Al3Ti, Al73Ti24Cr3, and Al67Ti25Cr8 were examined. Fully dense, homogeneous materials exhibiting an equiaxed grain structure were produced by conducting reaction and homogenization under pressure, or in a furnace at ambient pressure and subsequently densifying the porous preform by hot consolidation. The tetragonal DO22 structure was the primary reaction product for all compositions. Most of the Cr remained undissolved after reaction and a homogenization heat treatment at 1200 C or above was used to put the Cr into solution and form the desired L1(sub 2) phase. DOE

A SURVEY OF TECHNIQUES FOR CORROSION MONITORING
J. I. Mickalonis Oct. 1992 10 p
(Contract DE-AC09-89SR-18035)
(DE93-012131; WSRC-TR-92-472) Avail: CASI HC A02/MF A01

Corrosion monitoring techniques have improved with advances in instrumentation technology and corrosion research. Older techniques, such as coupon immersion, generally provide historical information. The new electrochemical techniques, which have not been used widely at SRS, allow on-line monitoring and correlation with process changes. These techniques could improve the corrosion assessment of the waste tanks to be used for In-Tank Precipitation and Extended Sludge Processing. A task was initiated to place an electrochemical probe into tank 48 for testing the utility of this technique for waste tank applications. DOE

N94-11316 Pennsylvania State Univ., University Park.
EXPERIMENTAL PROOF OF THE NEW IR-INDUCED MECHANISM OF CREVICE CORROSION AND ITS CONSEQUENCES REGARDING PROTECTION SCHEMES Ph.D. Thesis
Kyehyun Cho 1992 164 p
Avail: Univ. Microfilms Order No. DA9311610

Recent results have shown that crevice corrosion of iron occurs solely by a shift of the local electrode potential into the active region of the polarization curve, this shift of potential to the less oxidizing direction is caused by the IR drop in the crevice electrolyte. Thus, crevice corrosion occurs when IR greater than IR*, where IR is the voltage drop in the electrolyte between the cathodic site at the outer surface (where oxygen is plentiful) and the crevicing site, and IR* is the potential difference between the electrode potential at the outer surface (cathodic site) established by the oxidant (or power supply) and the electrode potential of the active/passive transition of the crevice electrolyte. The local electrode potential inside the crevice and the pH of the crevice solution were measured and correlated to visually observed changes occurring within the crevice of an iron sample during the crevicing process in various electrolytes. It has been known that acidification and build-up of chloride inside the crevice are not prerequisite conditions for crevicing to occur. But acidification and chloride anions have been known to promote crevice corrosion. Therefore, acidification and chloride ions were investigated for their roles in promoting the IR greater than IR* criterion. Also, the roles of oxidizing power of the electrolyte, anodic inhibitors, solution resistance, and electrolyte temperature were studied in order to confirm the IR drop mechanism and apply it in engineering design. Acidification and chloride ions promote crevicing by a shift of the passivation potential to more noble potentials (IR decreases) and by increasing the active loop currents (IR increases), thereby facilitating the IR greater than IR* condition. Finally, based on the IR greater than IR* criterion, crevice corrosion can be suppressed by (1) shifting the surface potential (corrosion potential) in the more noble direction (increasing IR*), (2) adding inhibitors to the electrolyte that significantly shift E(sub pass) to less noble values (increasing IR*) and decrease I(sub max) (decrease IR), (3) increasing the solution conductivity (decreasing IR), and (4) decreasing the electrolyte temperature since lower temperatures decrease the active loop on the polarization curve. Dissert. Abstr.

A METHOD OF INFLUENCE REGIONS IN THE THEORY OF VACANCY SWELLING OF METALS [METOD OBLASTEJ VLIYANIYA V TEOTII VAKANSIONNOGO RASPUKHANIYA METALLOV]
P. N. Ostapchuk and V. V. Slezov 1992 64 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-620579; KFTI-92-14) Avail: CASI HC A04 (US Sales Only)

A new method is developed to calculate point defect fluxes for various sinks. The method takes into account the volume fraction of sinks similar to the well known effective medium approach. But in contrast to the latter in our method, we introduce sink-free regions around each sink. The sizes of the sinks are determined self-consistently. As an illustration, the defect fluxes to a void and an edge dislocation are found. The vacancy swelling of metals under irradiation is discussed in terms of results obtained. DOE

EFFECT OF POWDER PROCESSING ON SLIP CASTING PARAMETERS AND SINTERING OF Si3N4-Y2O3-SiO2 Final Report
Gary Gilde and George Gazza Apr. 1993 16 p
(AD-A264474; ARL-TR-93) Avail: CASI HC A03/MF A01

A procedure was developed for slip casting Si3N4(-)Y2O3(-)SiO2 compositions. The silicon nitride was oxidized to supply the silica. The procedure resulted in 65 w/o slips with viscosities of 35 mPa(dot)s which, when cast, yielded compacts which were 56% of theoretical density. Slips with 70 w/o solids loading were also prepared having viscosities of 120 mPa(dot)s. The properties of the slips were influenced by the starting silicon nitride powder, dispersant, and milling media. The resulting compacts could be gas pressure sintered to full density, at temperatures as low as

1850 C, using nitrogen pressures as low as 4 MPa. Strengths as high as 750 MPa were achieved and the initial results show good creep resistance at 1350 C. DTIC

IN SITU XANES STUDIES OF THE PASSIVE FILM ON Fe AND Fe-26Cr
A. J. Davenport, H. S. Isaacs, J. A. Bardwell (National Research Council of Canada, Ottawa, Ontario.), and B. MacDougall (National Research Council of Canada, Ottawa, Ontario.) 1993 10 p Presented at the European Symposium on Passive Films, Paris, France, 15-19 Feb. 1993
(Contract DE-AC02-76CH-00016)
(DE93-010869; BNL-48620; CONF-930271-2) Avail: CASI HC A02/MF A01

In situ x-ray absorption near edge structure (XANES) has been used to study the passive film on iron and Fe-Cr-26 thin films under potential control in borate buffer. The technique enables information on both valence state and the amount of material lost through dissolution to be determined. The passive films on both Fe and Fe-Cr are formed with negligible dissolution. On reduction, iron is lost from both films due to reductive dissolution. In the case of Fe, it has been determined that some of the iron in the film is reduced back to-the-metallic state. Concurrent monitoring of the Fe and Cr edges has shown that in the case of Fe-Cr, loss of iron leads to enrichment of Cr in the film. DOE

THE EFFECT OF PROCESSING ON THE MICROSTRUCTURE AND TENSILE PROPERTIES OF A (GAMMA)-TiAl BASED ALLOY
G. E. Fuchs Feb. 1993 15 p Presented at the 7th World Conference and Exhibition on Titanium, San Diego, CA, 28 Jun. - 2 Jul. 1992
(Contract DE-AC12-76SN-00052)
(DE93-013221; KAPL-4737; CONF-920604-4) Avail: CASI HC A03/MF A01

Compositional and microstructural control, and alloying additions have been the primary methods used to increase the low temperature ductility of TiAl-based alloys. However, very little has been done to characterize the effect of processing on ductile gamma-TiAl alloys. The effect of processing on microstructure and properties of cast, wrought and powder metallurgy TiAl-based alloys with a similar nominal composition is examined. The alloy was Ti-48Al-2Nb-2Cr (at. %). After processing, all of the samples were heat treated in the alpha + gamma phase field. Microstructures were characterized by optical, scanning electron, and transmission electron microscopy. Tensile properties were evaluated in the temperature range 25-1000 C in air. The powder processed alloys exhibited the highest strength and ductility at test temperatures up to 850 C. All of the alloys exhibited similar tensile properties at 1000 C. Examination of fracture surfaces indicated that tensile failure occurred by predominantly transgranular cleavage at temperatures below 700 C. However, above 850 C, significant plastic deformation was observed, particularly in the powder metallurgy samples. The inter-relationships of processing-microstructure-mechanical properties of Ti-48Al-2Nb-2Cr (at. %) are discussed. DOE

FACILITY FOR STRESS CORROSION CRACKING TEST OF IRRADIATED MATERIAL IN HIGH TEMPERATURE WATER
Takashi Tsukada (Japan Atomic Energy Research Inst., Tokai.), Kiyoyuki Shiba (Japan Atomic Energy Research Inst., Tokai.), Hajime Nakajima (Japan Atomic Energy Research Inst., Tokai.), Minoru Kizaki (Japan Atomic Energy Research Inst., Tokai.), Kenji Sudo (Japan Atomic Energy Research Inst., Tokai.), G. E. C. Bell, Masao Ohmi, and Ichiro Goto Jun. 1992 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753189; JAERI-M-92-081) Avail: CASI HC A03

Irradiation assisted stress corrosion cracking (IASCC) is a synergistic effect of neutron irradiation, aqueous environment, and stress on nuclear core materials. In order to investigate the IASCC, a facility for stress corrosion cracking tests of irradiated materials was developed. The slow strain rate technique (SSRT) in high temperature and pressure water environment was employed. The post irradiation SSRT test facility consists of an SSRT test machine and a water circulation and purification system. In the design of the facility, attentions were paid to safe and reliable remote operation of heavily irradiated materials in hot cell. Main specification of the facility is as follows; maximum load capacity: 30 kN, strain rate range: 10(exp -7) s(sup -1) approximately 10(exp -3) s(sup -1), test temperature/pressure: 300 C and 10 MPa in maximum, water supply rate: 5 1/h, controllable range of dissolved oxygen (DO): 0.01 approximately 32 ppm. Water chemistry is monitored on DO, electric conductivity, and pH. Electrochemical potential and electric current are monitored and controlled on specimen. A preliminary test was carried out on the type 316 stainless steel irradiated up to 8 dpa in Oak Ridge Research Reactor under spectrally tailored condition. As a result of the test an occurrence of IASCC and a good performance of the facility were confirmed. DOE

PLATING UNDER REDUCED PRESSURE
J. W. Dini, T. G. Beat, W. C. Cowden, L. E. Ryan, and W. B. Hewitt (TRW, Inc., Redondo Beach, CA.) Jun. 1992 21 p Presented at the 1992 American Electroplaters and Surface Finishers Society Conference, Atlanta, GA, 22-25 Jun. 1992
(Contract W-7405-eng-48)
(DE93-011896; UCRL-JC-109782; CONF-9206129-4) Avail: CASI HC A03/MF A01

Plating under reduced pressure was evaluated for both electroless nickel and electrodeposited copper systems. The objective was to reduce pitting of these coatings thereby further enhancing their usage for diamond turning applications. Cursory experiments with electroless nickel showed reduced porosity when deposition was done at around 500 torr. Detailed experiments with electrodeposited copper at around 100 torr provided similar results. Scanning tunneling microscopy was effectively used to show the improvement in the copper deposits plated under reduced pressure. Benefits included reduced surface roughness and finer and denser grain structure. DOE

WELD OVERLAY COATINGS FOR EROSION CONTROL
B. Levin, J. N. DuPont, and A. R. Marder 3 Mar. 1993 22 p
(Contract DE-FG22-92PC-92542)
(DE93-013592; DOE/PC-92542/T1) Avail: CASI HC A03/MF A01

A literature review was made. In spite of similarities between abrasive wear and solid particle erosion, weld overlay hardfacing alloys that exhibit high abrasion resistance may not necessarily have good erosion resistance. The performance of weld overlay hardfacing alloys in erosive environments has not been studied in detail. It is believed that primary-solidified hard phases such as carbides and intermetallic compounds have a strong influence on the erosion resistance of weld overlay hardfacing alloys. However, relationships between size, shape, and volume fraction of hard phases in hardfacing alloys and erosion resistance were not established. Almost all hardfacing alloys can be separated into two major groups based upon chemical compositions of the primary solidified hard phases: (1) carbide hardening alloys (Co-base/carbide, WC-Co, and some Fe base superalloys); and (2) intermetallic hardening alloys (Ni-base alloys, austenitic steels, iron-aluminides). GRAIN BOUNDARY CREEP IN COPPER
A. Ayensu (Cape Coast Univ., Ghana.), G. K. Quainoo (Cape Coast Univ., Ghana.), and S. K. Adjepong (Cape Coast Univ., Ghana.) Oct. 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-610974; IC-92/327) Avail: CASI HC A03 (US Sales Only)

Hard-drawn polycrystalline copper wires of 99.9% purity and grain size ranging from 90 to 125 microns produced by Kabelmetal (Ghana) Ltd. were creep tested within the temperature range of 0.42 to 0.57 T(sub m) at atmospheric pressure under uniaxial stress of 7.08 to 21.24 MPa. The stress exponent, n, determined ranges from 2.0 to 2.4 and the activation energy, delta(H), ranges from 61.3 to 63.2 kJ/mol. It was observed that n decreased with temperature and delta(H) decreased with stress. The deformation mechanism is attributed to grain boundary sliding and the self-diffusion of copper atoms within the grain boundary calculated on the Cobble model ranges from 2.2 x 10(exp -11) sq cm/s to 2.2 x 10(exp -10) sq cm/s. Electron spectroscopy has become one of our most important tools for the study of electronic structure of solids and at surfaces. The passivation and inhibition of corrosion, utilizing the spectroscopic techniques of x-ray photoelectron spectroscopy (XPS), Auger electron spectroscopy (AES), and NEXAFS were studied. In particular, the passivation of Al and Al-alloys towards attack by Cl(-), and the utility of Zr-Ir alloys to serve as diffusion/reaction barriers on silicon and carbon at elevated temperatures was studied. DTIC

CORROSION BEHAVIOR OF METAL MATRIX COMPOSITES Final Report, 1 Jul. 1989 - 30 Sep. 1992
Harovel G. Wheat 29 Jan. 1993 80 p
(Contract N00014-89-J-3116)
(AD-A265352) Avail: CASI HC A05/MF A01

A research program was conducted to assess the corrosion behavior of two categories of copper metal matrix composites: commercially available composites and composites in development. The commercially available composite studied was dispersion strengthened copper (2.7 vol % Al2O3/Cu) which was found to possess comparable corrosion resistance to copper. In addition, it did not appear to be susceptible to stress corrosion cracking when U-bend specimens were tested in 3.5 wt % NaCl or artificial seawater for a period of 4 months. Stress corrosion cracking was also not observed under proof ring loading in 3.5 wt % NaCl for a period of 8 months at an applied stress of 95% of the yield stress. The composites in development studied were HEHR Gr(sub p)/Cu composites containing 1.2, 5, 15, 25, and 40 vol % graphite; 50 vol % GR (sub f) Cu; and 70 vol % W (sub f) Cu. These composites experienced varying degrees of galvanic corrosion during polarization. Benzotriazole, however, offers excellent potential as a corrosion inhibitor for these composites. DTIC

FATIGUE IN SINGLE CRYSTAL NICKEL SUPERALLOYS Technical Progress Report, 16 Mar. - 15 Apr. 1993
Daniel P. DeLuca and Charles Annis 15 Apr. 1993 6 p
(Contract N00014-91-C-0124)
(AD-A266116; PW/GESP-FR21998-18) Avail: CASI HC A02/MF A01

This program investigates the seemingly unusual behavior of single crystal airfoil materials. The fatigue initiation processes in single crystal (SC) materials are significantly more complicated and involved than fatigue initiation and subsequent behavior of a (single) macrocrack in conventional, isotropic materials. To understand these differences is the major goal of this project. DTIC

MICROSTRUCTURE-BASED FATIGUE LIFE PREDICTION METHODS FOR NAVAL STEEL STRUCTURES Quarterly Report
K. S. Chan, R. C. McClung, and T. Y. Torng 30 Jan. 1993 17 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-C-0214)
(AD-A265429) Avail: CASI HC A03

The ongoing development of new HSLA (high-strength, low alloy) steels for use in ship and submarine structures permits increases in design stress levels, which may in turn increase the significance of fatigue cracking as a threat to structural integrity. The subject program was motivated by the desire for improved understandings of the relationships between microstructure and fatigue damage in naval steel structures, with particular application to the prediction of fatigue life. Among the intended products of the study are improved methods for fatigue life prediction which give appropriate attention to different potential microstructures and associated microstructural influences on fatigue crack initiation and growth rates. The methods could be used to provide guidance in optimizing alloy chemistry, processing, and welding protocols for improved fatigue resistance, while also expediting improved fitness-for-service assessments of actual or postulated cracking. NiAl ALLOYS FOR STRUCTURAL USES Final Report, 27 Oct. 1987 - 31 Dec. 1991
D. A. Koss 31 Dec. 1991 33 p
(Grant NAG3-827)
(NASA-CR-194113; NAS 1.26:194113) Avail: CASI HC A03/MF A01

Alloys based on the intermetallic compound NiAl are of technological interest as high temperature structural alloys. These alloys possess a relatively low density, high melting temperature, good thermal conductivity, and (usually) good oxidation resistance. However, NiAl and NiAl-base alloys suffer from poor fracture resistance at low temperatures as well as inadequate creep strength at elevated temperatures. This research program explored macroalloying additions to NiAl-base alloys in order to identify possible alloying and processing routes which promote both low temperature fracture toughness and high temperature strength. Initial results from the study examined the additions of Fe, Co, and Hf on the microstructure, deformation, and fracture resistance of NiAl-based alloys. Of significance were the observations that the presence of the gamma-prime phase, based on Ni3Al, could enhance the fracture resistance if the gamma-prime were present as a continuous grain boundary film or 'necklace'; and the Ni-35Al-20Fe alloy was ductile in ribbon form despite a microstructure consisting solely of the B2 beta phase based on NiAl. The ductility inherent in the Ni-35Al-20Fe alloy was explored further in subsequent studies. Those results confirm the presence of ductility in the Ni-35Al-20Fe alloy after rapid cooling from 750 - 1000 C. However exposure at 550 C caused embrittlement; this was associated with an age-hardening reaction caused by the formation of Fe-rich precipitates. In contrast, to the Ni-35Al-20Fe alloy, exploratory research indicated that compositions in the range of Ni-35Al-12Fe retain the ordered B2 structure of NiAl, are ductile, and do not age-harden or embrittle after thermal exposure. Thus, our recent efforts have focused on the behavior of the Ni-35Al-12Fe alloy. A second parallel effort initiated in this program was to use an alternate processing technique, mechanical alloying, to improve the properties of NiAl-alloys. Mechanical alloying in the conventional sense requires ductile powder particles which, through a cold welding and fracture process, can be dispersion strengthened by submicron-sized oxide particles. Using both the Ni-35Al-Fe alloys to contain approx. 1 v/o Y2O3. Preliminary results indicate that mechanically alloyed and extruded NiAl-Fe + Y2O3 alloys when heat treated to a grain-coarsened condition, exhibit improved creep resistance at 1000 C when compared to NiAl; oxidation resistance comparable to NiAl; and fracture toughness values a factor of three better than NiAl. As a result of the research initiated on this NASA program, a subsequent project with support from Inco Alloys International is underway. Derived from text

ADVANCES IN LOW CARBON, HIGH STRENGTH FERROUS ALLOYS Research and Development Report
E. J. Czyryca and M. G. Vassilaros Apr. 1993 51 p
(AD-A265264; CDNSWC/SME-92/64) Avail: CASI HC A04/MF A01

Carderock Division, Naval Surface Warfare Center participated in the Indo-US Pacific Rim Workshop on 'Advances in Low Carbon, High Strength Ferrous Alloys' held in New Delhi, India, 25 to 28 March 1992. E.J. Czyryca and M.G. Vassilaros gave invited presentations on the status of Navy program on steel plate and weld metal research and development, respectively. The workshop was jointly sponsored by Office of Naval Research, Naval Research Laboratory, US Army Research Office - Far East, and the National Metallurgical Laboratory of India. This report contains papers based on the two presentations. Paper 1 - 'Advances in High Strength Steel Technology for Naval Hull Construction,' covers an overview of US Navy steel plate research programs. Paper 2 - 'The Development of High-Strength, Cooling-Rate Insensitive Ultra-Low-Carbon Weld Metals,' presents the status of research in high-strength steel weld metal systems based on ultra-low carbon bainitic (ULCB) metallurgy. ULCB weld metals show a potential for wire electrode formulations for HSLA steel welding, where the as deposited weld metal strength is independent of weld metal cooling rate with a good low-temperature toughness. ZERODUR POLISHING PROCESS FOR HIGH SURFACE QUALITY AND HIGH EFFICIENCY
A. Tesar and B. Fuchs Aug. 1992 6 p Presented at the OPTCON 1992: Optical Fabrication and Testing Workshop, Boston, MA, 17 Nov. 1992
(Contract W-7405-eng-48)
(DE93-012596; UCRL-JC-111396; CONF-9211104-8) Avail: CASI HC A02/MF A01

Zerodur is a glass-ceramic composite of technical importance in applications where temperature instabilities influence optical and mechanical performance, such as in earthbound and spaceborne telescope mirror substrates. Polished Zerodur surfaces of high quality have been required for laser gyro mirrors. Polished surface quality of substrates affects performance of high reflection coatings. Thus, the interest in improving Zerodur polished surface quality has become more general. Beyond eliminating subsurface damage, high quality surfaces are produced by reducing the amount of hydrated material redeposited on the surface during polishing. With the proper control of polishing parameters, such surfaces exhibit roughnesses of less than 1 A rms. Zerodur polishing was studied to recommend a high surface quality polishing process which could be easily adapted to standard planetary continuous polishing machines and spindles. This summary contains information on a polishing process developed at LLNL which reproducibly provides high quality polished Zerodur surfaces at very high polishing efficiencies. DOE

SENSING GLASS TRANSITIONS IN THIN POLYMER FILMS ON ACOUSTIC WAVE MICROSENSORS
J. W. Grate Mar. 1993 24 p Presented at the American Society of Testing and Materials Meeting on Glass Transition, Atlanta, GA, 4-5 Mar. 1993
(Contract DE-AC06-76RL-01830)
(DE93-010805; PNL-SA-21812; CONF-930398-2) Avail: CASI HC A03/MF A01

Acoustic wave microsensors are capable of sensing transition behaviors of homogeneous amorphous polymers applied as thin films to the surface of the sensors. The device and wave characteristics of four such microsensors, and examples of their uses in monitoring polymer properties, are described. The devices are the thickness-shear mode (TSM), surface acoustic wave (SAW), flexural plate wave (FPW), and shear horizontal acoustic plate mode (SH-APM) devices. Using the FPW device, the change in the polymer coefficient of thermal expansion at the static glass transition temperature is sensed as a change in slope of the frequency-temperature plot. This behavior reflects the fact that the frequency measures acoustic velocity, which decreases as the polymer modulus decreases. Modulus decreases as the polymer volume increases. Frequency-dependent relaxation properties are detected with a sigmoidal change in slope of the frequency-temperature plot and a maximum in signal amplitude. The minimum in signal amplitude is analogous to the maximum in the loss tangent in dynamic mechanical analysis, or the maximum in sound damping in bulk-wave ultrasonic studies. DOE

Proteins and glycoproteins of enzymes behave with respect to electron transport, but not ion transport, as good electrical insulators. We have shown that these insulators can be made sufficiently electron conducting to allow the flow of a current between reaction centers of redox enzymes and electrodes equaling or exceeding the current associated with the turnover of the enzymes. In order for such a current to flow, it is necessary to introduce into the enzyme proteins of glycoproteins fast electron relaying centers, so as to reduce the electron transfer distances. DTIC

Analytical electron microscopy (AEM) was performed with an AEM system equipped with a field emission gun, an electron energy-loss spectrometer, and an energy-dispersive x-ray spectrometer. The microstructure consists of alternating lamellae of CoO and Ca-stabilized cubic-ZrO2, each up to 1 micron wide, and a thin (100-200 nm) irregular layer of Co3O4 spinel extending into the CoO from the flat ZrO2 interface. IMPROVING RESERVOIR CONFORMANCE USING GELLED POLYMER SYSTEMS
D. W. Green and G. P. Willhite Apr. 1993 6 p
(Contract DE-AC22-92BC-14881)
(DE93-014532; DOE/BC-14881/2) Avail: CASI HC A02/MF A01

The general objectives are as follows: (1) to identify and develop gelled polymer systems which have potential to improve reservoir conformance of fluid displacement processes; (2) to determine the performance of these systems in bulk and in porous media; and (3) to develop methods to predict the capability of these systems to recover oil from petroleum reservoirs. This work focuses on three types of gel systems: an aqueous polysaccharide (KUSPI) system that gels as a function of pH, the chromium-based system where polyacrylamide and xanthan are crosslinked by CR(3), and an organic crosslinked system. Development of the KUSPI system and evaluation and identification of a suitable organic crosslinked system will be done. The laboratory research is directed at the fundamental understanding of the physics and chemistry of the gelation process in bulk form and in porous media. This knowledge will be used to develop conceptual and mathematical models of the gelation process. Mathematical models will then be extended to predict the performance of gelled polymer treatments in oil reservoirs. Accomplishments for this period are presented for the following tasks: development and selection of gelled polymer systems, physical and chemical characterization of gel systems; and mathematical modeling of gel systems. DEVELOPMENT OF BIOELASTIC MATERIALS FOR THE PREVENTION OF ADHESIONS: POLYPENTA- AND POLYTETRAPEPTIDES Final Report, 15 Sep. 1989 - 14 Mar. 1993
14 Mar. 1993 162 p
(Contract N00014-89-C-0282)
(AD-A264851) Avail: CASI HC A08/MF A02

The purpose of the contract was the development of bioelastic materials for the application of preventing post-surgical and post-trauma adhesions by preparing compliant sheets which can be placed between repair sites and which act as barriers to the formation of adhesions between the repairing sites. Specifically to be prepared were quantities of a series of polypentapeptides and polytetrapeptides which were gamma-irradiation cross-linked to form elastomeric sheets and which were supplied to the Naval Medical Research and Development Command, Combat Casualty Care Unit for the animal model efficacy studies carried out at the Naval Medical Research Institute. In addition, in the process of carrying out the specific objectives, considerations of further applications was stimulated and these stimuli, coming from interactions with Navy personnel and others, have resulted in the development of intellectual property with the support of this contract. THE PROPERTIES OF PERFLUOROPOLYETHERS USED FOR SPACE APPLICATIONS
William R. Jones, Jr. Jul. 1993 16 p
(RTOP 505-53-1A)
(NASA-TM-106275; E-8010; NAS 1.15:106275) Avail: CASI HC A03/MF A01

The perfluoropolyether (PFPE) class of liquid lubricants has been used for space applications for over two decades. At first, these fluids performed satisfactorily as early spacecraft placed few demands on their performance. However, as other spacecraft components have become more reliable and lifetimes have been extended, PFPE lubricant deficiencies have been exposed. Therefore, the objective of this paper is to review the PFPE properties that are important for successful long term operation in space. Author

SOME ENVIRONMENTAL ASPECTS OF THE APPLICATION OF FIBRE REINFORCED PLASTICS IN STRUCTURES
R. Marissen 28 Jan. 1993 13 p
(LM-998; ETN-93-94334) Copyright Avail: CASI HC A03/MF A01

The savings on resource consumption and the associated waste production concerning the recycling of glass fiber composites are discussed. Recycling can be understood literally in a sense that, after completing its life cycle, a product is reprocessed to an identical product. A broader perception of recycling allows the reprocessing of waste products to less valuable products. Considering recycling aspects only, neglects the use of resources and waste production related to the use of the product during its life time. Some of these aspects are discussed. It is demonstrated that the application of composites in transport may reduce the use of resources and the production of waste, to an extent which is potentially much larger than that of the involved composite material itself. ADVANCED ZINC PHOSPHATE CONVERSION AND PRE-CERAMIC POLYMETALLOSILOXANE COATINGS FOR CORROSION PROTECTION OF STEEL AND ALUMINUM, AND CHARACTERISTICS OF POLYPHENYLETHERETHERKETONE-BASED MATERIALS
T. Sugama and N. R. Carciello Jul. 1992 14 p Prepared for Army Research Office, Research Triangle Park, NC
(Contract DE-AC02-76CH-00016)
(DE93-008717; BNL-48106) Avail: CASI HC A03/MF A01 (US Sales Only)

Anhydrous zinc phosphate (Zn(center dot)Ph) coatings deposited by immersing the steel in transition Co, Ni, and Mn cation-incorporated phosphating solutions were investigated. Two features for the anhydrous 340C-heated (Zn(center dot)Ph) were addressed; one was to determine if electron trapping of adsorbed CO(sup 2+) and Ni(sup 2+) ions acts to inhibit the cathodic reaction on the (Zn(center dot)Ph), and the second was to determine the less susceptibility of the (alpha)-Zn(sub 3)(PO(sub 4))(sub 2) phase to alkali-induced dissolution. The factors governing film-forming of pre-ceramic polymetallosiloxane (PMS) coatings for Al substrates were investigated. Four factors were important in obtaining a good film: (1) formation of organopolymetallosiloxane at sintering temperatures of 150C; (2) pyrolytic conversion at 350C into an amorphous PMS network structure in which the Si-O-M linkage were moderately enhanced; (3) noncrystalline phases; and (4) formation of interfacial oxane bond between PMS and Al oxide. Formation of well-crystallized polyphenyletheretherketone (PEEK) in vicinity of silica aggregates was found in the molted body made in N2. Crystalline PEEK contributed to thermal and hydrothermal stabilities of mortar specimens at temperatures up to 200C, and resistance in 5 wt % H2SO4 solution at 80C. DOE

PREPARATION OF CARBON MONOLITHS HAVING TAILORED PORE STRUCTURE FROM POROUS POLYMER PRECURSORS
R. R. Lagasse 1993 3 p Presented at the Biennial Conference on Carbon, Buffalo, NY, 13-18 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011576; SAND-93-0825C; CONF-930615-1) Avail: CASI HC A01/MF A01

This work concerns preparing tailored porous carbon monoliths by pyrolyzing porous polymer precursors. Prior work in this laboratory demonstrated that a low density (0.05 g/cu cm), high void fraction (97 vol%) carbon monolith could be prepared by pyrolyzing a porous poly(acrylonitrile) (PAN) precursor. A higher density, more robust carbon material is preferred for certain applications, such as electrodes for electrochemical devices. The present work demonstrates that porous carbon monoliths having mass density of 0.7 g/cu cm can be prepared from a porous PAN precursor if the pyrolysis is controlled carefully. The macropore structure of the carbon is adjusted by changing the pore structure of the PAN precursor, and the finer scale structure (such as the crystallite size L(sub c)) is adjusted by varying the pyrolysis or heat treatment temperature. POLYMERIC NITROGEN
C. Mailhiot, L. H. Yang, and A. K. McMahan Aug. 1992 7 p Presented at the 1992 Air Force High Energy Density Materials Contractors Meeting, Lancaster, CA, 12-14 Apr. 1992 Revised
(Contract W-7405-eng-48)
(DE93-012600; UCRL-JC-110049-Rev-1; CONF-9204235-2-Rev-1) Avail: CASI HC A02/MF A01

Ab initio local-density functional total-energy calculations indicate that a polymeric form should be the stable phase of nitrogen above approximately 35 GPa, and that such a polymeric phase is likely to be both energetic and metastable at atmospheric pressure. These results also suggest that such a polymeric form of nitrogen may survive metastably at atmospheric pressure as an energetic, high-melting temperature, insulating solid, with a specific enthalpy of 6.7-14.1 MJ/kg. While this does not exceed the Air Force HEDM goal of 15 MJ/kg, such a material may nevertheless compare favorably with existing monopropellants. DOE

LOW TEMPERATURE SYNTHESIS OF MONOLITHIC TRANSPARENT Ta2O5 GELS FROM HYDROLYSIS OF METAL ALKOXIDE
Narottam P. Bansal Jul. 1993 20 p
(RTOP 510-01-50)
(NASA-TM-106246; E-7966; NAS 1.15:106246) Avail: CASI HC A03/MF A01

Tantalum oxide gels in the form of transparent monoliths and powder were prepared from hydrolysis of tantalum pentaethoxide under controlled conditions using different mole ratios of Ta(OC2H5)5:C2H50H:H20:HCl. Alcohol acts as the mutual solvent and HCl as the deflocculating agent. For a fixed alkoxide:water:HCl ratio, time of gel formation increased with the alcohol to alkoxide mole ratio. Thermal evolution of the physical and structural changes in the gel was monitored by differential thermal analysis, thermogravimetric analysis, x-ray diffraction, and infrared spectroscopy. On heating to approximately 400 C, the amorphous gel crystallized into the low temperature orthorhombic phase Beta-Ta2O5, which transformed into the high temperature tetragonal phase Alpha-Ta2O5 when further heated to approximately 1450 C. The volume fraction of the crystalline phase increased with the firing temperature. The Alpha-Ta205 converted back into the low temperature phase, Beta-Ta2O5, on slow cooling through the transformation temperature of 1360 C indicating a slow but reversible transformation. DAMAGE THRESHOLDS OF FLUORIDE MULTILAYERS AT 355 nm
R. Chow, M. R. Kozlowski, G. E. Loomis, and F. Rainer Oct. 1992 12 p Presented at the Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 28-30 Oct. 1992
(Contract W-7405-eng-48)
(DE93-009523; UCRL-JC-111482; CONF-921047-1) Avail: CASI HC A03/MF A01

Fluoride multilayer coatings were evaluated for use in 355 nm high reflector applications. The LaF3/Na3AlF6, NdF3/Na3AlF6, and GdF3/Na3AlF6 multilayers had laser damage thresholds of 20, 17.9, and 7.4 (measured at 10-ns pulsewidths), respectively. High tensile stresses in the coatings restricted this evaluation to only 5-layer-pair partial reflectors (49-52%). The LaF3/Na3AlF6, NdF3/Na3Al6, and GdF3/Na3AlF6 multilayers had tensile stresses of approximately 1.1 x 10(exp 9), 1.3 x 10(exp 9), and 9.3 x 10(exp 8) dynes/sq cm, respectively. Substrate material and glow-discharge processing of the substrates were found to influence the density of stress-induced coating fractures and damage thresholds in some cases. If stress fracturing and scatter can be controlled, these fluoride material combinations are suited for 3(omega) applications. DOE

SYNTHESIS AND THERMAL EVOLUTION OF STRUCTURE IN ALKOXIDE-DERIVED NIOBIUM PENTOXIDE GELS
Narottam P. Bansal Jul. 1993 21 p
(RTOP 510-01-50)
(NASA-TM-106259; E-7984; NAS 1.15:106259) Avail: CASI HC A03/MF A01

Niobium pentoxide gels in the form of transparent monoliths and powder have been synthesized from the controlled hydrolysis and polycondensation of niobium pentaethoxide under different experimental conditions using various mole ratios of Nb(OC2H5)5:H2O:C2H5OH:HCl. Alcohol acted as the mutual solvent and HCl as the deflocculating agent. In the absence of HCl, precipitation of colloidal particles was encountered on the addition of any water to the alkoxide. The gels were subjected to various thermal treatments and characterized by differential thermal analysis, thermogravimetric analysis, x-ray diffraction, and infrared spectroscopy. After drying at 400 C, the gels were amorphous to x-rays. The amorphous powder crystallized into the low-temperature orthorhombic form of Nb2O5 at approximately 500 C, which transformed irreversibly into the high-temperature monoclinic alpha-Nb2O5 between 900 to 1000 C. The kinetics of crystallization of the amorphous niobium pentoxide have been investigated by non-isothermal differential scanning calorimetry. The crystallization activation energy was determined to be 399 kJ/mol. Author (revised)

STRUCTURAL DEVELOPMENT IN CERAMIC PRECURSOR SOLS AND GELS Final Report, 15 Mar. 1989 - 14 Mar. 1992
Martha L. Mecartney Mar. 1993 52 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-89-C-0050)
(AD-A264354; AFOSR-93-0218TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The effect of water of hydrolysis on nucleation, crystallization, and microstructural development of sol-gel derived single phase LiNbO3 thin films has been studied using transmission electron microscopy (TEM), atomic force microscopy (AFM), x-ray diffraction (XRD), and differential scanning calorimetry (DSC). A percursor solution of double ethoxides of lithium and niobium in ethanol was used for the preparation of sol. DSC results indicated that adding water to the solution for hydrolysis of the double ethoxides lowered the crystallization temperature from 500 deg C (no water) to 390 deg C (2 moles water per mole ethoxide). The amount of water has no effect on the short range order in amorphous LiNbO3 gels but rendered significant microstructural variations for the crystallized films. AFM studies indicated that surface roughness of dip coated films increased with increasing water of hydrolysis. DTIC

FORMULATING INFRARED COATINGS FOR DEFENCE APPLICATIONS
L. V. Wake and R. F. Brady Mar. 1993 38 p
(MRL-RR-1-93; AR-008-254) Avail: CASI HC A03/MF A01

Relevant physical laws governing the response of coatings to solar and infrared radiation were reviewed. The reflection of infrared radiation by a paint is controlled primarily by the refractive index and particle size of the pigments in the coating. Pigments were evaluated for reflectance, transparence and hiding power in the near infrared region, and guidelines for pigment selection for various applications given in terms of their optical properties in the near infrared region. Raw materials selection, manufacture, and evaluation of coatings were discussed with respect to tailoring infrared reflectance. By employing the principles developed and using pigments with appropriate properties, organic coatings were developed which are consistent with the visible color requirements of the Australian and US Navies. Significant increases in the reflection of infrared radiation were demonstrated by the new formulations. The need for a very clear understanding of the threat systems and the operational conditions of service platforms was emphasized. It is only with this understanding that optimum paint schemes can be devised. However, it can be stated that the use of the solar infrared reflecting paints described would reduce conspicuity of isolated platforms to surveillance and seeker systems operating in the mid and far infrared without detriment to visual camouflage characteristics. FIELD EVALUATION OF SIX PROTECTIVE COATINGS APPLIED TO T-56 TURBINE BLADES AFTER 2500 HOURS OF ENGINE USE
S. G. Russo Apr. 1993 25 p Original contains color illustrations
(ARL-TR-27; AR-008-336) Copyright Avail: Issuing Activity

An assessment of the performance of six different aluminide coatings applied to Allison T-56 high-pressure turbine blades after 2500 hours of engine operation is outlined. The results confirm the superior resistance of the precious metal (platinum and platinum/rhodium) modified aluminide coatings to high temperature oxidation and hot-corrosion, as previously indicated by the earlier progressive evaluations at 500, 1500 and 2000 hour intervals. Special attention was given to the use of qualitative analysis using energy dispersive x ray spectroscopy. This technique identified substantial residue quantities of precious metal (Pt and Pt/Rh) in their respective aluminide coated surfaces. The results show that the precious-metal modified aluminides are capable of affording protection to the T-56 substrate superalloy designated IN-738LC up to, and hopefully beyond, the desired 3000 hour interval. VACUUM STABILITY REQUIREMENTS OF POLYMERIC MATERIAL FOR SPACECRAFT APPLICATION
J. W. Craig 24 Feb. 1994 63 p Revised
(NASA-TM-109216; NAS 1.15:109216; SP-R-0022A) Avail: CASI HC A04/MF A01

The purpose of this document is to establish outgassing requirements and test guidelines for polymeric materials used in the space thermal/vacuum environment around sensitive optical or thermal control surfaces. The scope of this document covers the control of polymeric materials used near or adjacent to optical or thermal control surfaces that are exposed to the thermal/vacuum environment of space. This document establishes the requirements and defines the test method to evaluate polymeric materials used in the vicinity of these surfaces in space applications.

CRYSTALLINITY AND DIELECTRIC PROPERTIES OF PEEK, A THERMOPLASTIC POLY(ETHER ETHER KETONE) Technical Report
Thomas W. Giants 1 May 1993 33 p
(Contract F04701-88-C-0089)
(AD-A266027; TR-93(3935)-10; SMC-TR-93-29) Avail: CASI HC A03/MF A01

The overall objective was to investigate the interdependence of specific dielectric properties of polymers on their fundamental molecular parameters in order to optimize the application of these polymeric materials in critical SMC systems. SMC systems utilize polymeric materials in applications involving high voltage (HV) insulation in systems aboard DSCS, Nilstar, and several classified spacecraft. Studies of polymer dielectrics have shown that changes in polymer morphology can influence fundamental electrical properties leading to premature breakdown. This investigation focused on the effect of polymer morphology on the electrical characteristics of PEEK, a high temperature insulating thermoplastic, as part of an effort in understanding the causes of dielectric breakdown. This amorphous material was thermally annealed to produce a range of crystallinities. The results of this effort showed that as the crystalline/amorphous ratio of the polymer increases, the dielectric breakdown strength is reduced. Electrical conductivity of the material was also shown to decrease. When translated to resins, blends, and advanced composites where environmental aging or thermal cycling can influence the morphology of the material, any reliance on the maintenance of stable electrical properties may have to be carefully considered. The introduction of advanced materials with tailored properties that involve different families of polymers will require a sophisticated understanding of the morphology of materials and the processes by which it varies. This will not only be important for enhancing mechanical properties of materials but also for recognizing the subtle influences that affect electrical properties of materials. DTIC

Theoretical models describing the dynamic behavior of the expansion and contraction of polyelectrolyte gels present numerically challenging problems. This paper describes how a method of weighted residuals approach has been used to solve the two-dimensional governing system of equations by finite element analysis. The modulation of the imbibition/expulsion of solvent by a gel disk is studied as an example.

The piston ring-cylinder liner area of the internal combustion engine must withstand very-high-temperature gradients, highly-corrosive environments, and constant friction. Improving the efficiency in the engine requires ring and cylinder liner materials that can survive this abusive environment and lubricants that resist decomposition at elevated temperatures. Wear and friction tests have been done on many material combinations in environments similar to actual use to find the right materials for the situation. This report covers tribology information produced from 1986 through Jul. 1991 by Battelle columbus Laboratories, Caterpillar Inc., and Cummins Engine Company, Inc. for the Ceramic Technology Project (CTP). All data in this report were taken from the project's semiannual and bimonthly progress reports and cover base materials, coatings, and lubricants. The data, including test rig descriptions and material characterizations, are stored in the CTP database and are available to all project participants on request. The objective of this report is to make available the test results from these studies, but not to draw conclusions from these data. DOE

POLYMER-POLYMER INTERACTIONS Final Report, 15 Sep. 1989 - 14 Nov. 1992
Isaac C. Sanchez and Donald R. Paul May 1993 16 p
(Grant AF-AFOSR-0479-89)
(AD-A265304; AFOSR-93-0358TR) Avail: CASI HC A03/MF A01

Our approach for understanding polymer-polymer interactions is to measure heats of mixing of small molecule analogs. In particular, focus was on small molecule analogs of polystyrene (PS) and poly (2, 6 dimethyl phenylene oxide) (PPO). This well-known system is miscible, but the origin of its miscibility has perplexed investigators for over 25 years. Our measurements and associated molecular mechanics/Monte Carlo calculations firmly established that the two methyl groups on PPO play a significant role in affecting miscibility. Two equation of state models for hydrogen bonding interactions were developed. They represent a significant advance in our understanding of hydrogen bonding interactions in both polymeric and non-polymeric systems. The models were successfully applied to a variety of systems that include supercritical fluids. Solubility of gases in liquid polymers was treated theoretically using the lattice-fluid model. SYNTHESIS, CHARACTERIZATION, AND MODIFICATION OF POLY(ORGANOPHOSPHAZENES), THAT BEAR BOTH 2,2,2-TRIFLUOROETHOXY AND PHENOXY GROUPS

Harry R. Allcock and Young B. Kim 18 May 1993 51 p
(Contract N00014-91-J-1194)
(AD-A264913; TR-12) Avail: CASI HC A04/MF A01

High molecular weight polyphosphazenes that bear varying ratios of phenoxy and 2,2,2-trifluoroethoxy groups were synthesized by the reactions of (NPC12)n with sodium phenoxide, PhO(-)Ne, and sodium 2,2,2-trifluoroethoxide, CF3CH2O(-)Na(+), using either competitive or sequential exposure to the two nucleophiles. The relative amounts of NP(OCH2CF3)(sub 2), NP(OCH2CF3)(OPh), and NP(OPh)(sub 2) units in the polymer are dependent on both the synthesis method and the amounts of CF3CH2O(-)Na(+) and PhO(-)Na(+) used for the synthesis. The sequential reaction of poly(dichlorophosphazene), (NPC12)(sub n), with CF3CH2O(-)Na(+) followed by PhO(-)Na(+) yields mixtures of polymers that have very different compositions depending on the presence or absence of tetra-n-butyl ammonium bromide or 15-crown-5 ether. The reactions are complicated by the fact that phenoxy groups in NP(OCH2CF3)(OPh) units are replaced by 2,2,2-trifluoroethoxy groups at elevated temperatures or at 25 C in the presence of either 15-crown-5 ether or tetra-n-butyl ammonium bromide. The sodium salt of 3-hydroxypropanol replaces both 2,2,2-trifluoroethoxy and phenoxy groups in these polymers at room temperature in the presence of either tetra-n-butyl ammonium bromide or 15-crown-5 ether. These side group exchange reactions are affected by steric effects. The mechanisms of these reactions are interpreted from the perspective that the reaction of CF3CH2O(-) Na+ alone with the small molecule model compound, (NPCl2)(sub 3), yields significant amounts of geminally substituted products in the presence of either tetra-n-butyl ammonium bromide or 15-crown-5 ether. RADIATION-INDUCED MODIFICATIONS OF ALLYLAMINO-SUBSTITUTED POLYPHOSPHAZENES

M. F. Welker, H. R. Allcock, G. L. Grune, R. T. Chern, and V. T. Stannett 18 May 1993 17 p
(Contract N00014-91-J-1194)
(AD-A264914; TR-9) Avail: CASI HC A03/MF A01

A collaborative effort to synthesize amino-substituted polyphosphazenes and examine their sensitivity to radiation has recently been undertaken. The objective was to determine the value of using such polymers as new and better resist materials for microlithographic applications. An initial study was carried out using elastomeric phenoxy-substituted polyphosphazenes as models for radiation and grafting. However, it became necessary to synthesize several new amino-substituted polyphosphazenes for several reasons. First, the usefulness of elastomeric polymers for resist applications is severely limited by their inability to remain dimensionally stable at normal temperatures. Glassy polymers have been shown to provide the necessary thermal properties required for resist films deposited on SiO2 wafers. Second, the amino-substituted polyphosphazenes are excellent film-forming polymers with high molecular weights. Finally, it seemed possible that these polymers would exhibit similar reactive ion etching resistance to those of a phenoxy-substituted counterpart, and experimental work was performed to determine reactive ion etching values for the most radiation-sensitive of the new polymer candidates. A SIMPLE MODEL OF MELT FRACTURE Final Technical Report, 1 Sep. 1991 - 31 Dec. 1992

James Greenberg 31 Dec. 1992 60 p
(Grant AF-AFOSR-0352-91)
(AD-A265311; AFOSR-93-0323TR) Avail: CASI HC A04/MF A01

The PI produced an excellent explanation of the unpleasant shark-skinning observed in certain polymer extrusion processes. This work was brought to the attention of researchers at Corning and Hoechst Celanese and Greenberg and Demay will work this summer with members of the Materials Sciences Center at the Ecole Nationale Superieure des Mines de Paris led by J.F. Agassant. One goal of this work is to see if the same oscillatory phenomena is present when one replaces the slip boundary condition by a no slip one and looks instead at materials whose shear stress-strain rate constitutive equation has a spinodal type nonlinearity. A difficult question also worth pursuing is whether now understanding the nature of the flow instability - a switch from a slip to a no slip boundary condition at the wall of the capillary tube - if it is possible to control the inlet flow to the capillary in the unstable regime in such a way as to reduce the oscillations and shark skinning of the final product. CHEMICAL VAPOR DEPOSITION OF REFRACTORY METALS AND CERAMICS 2. MATERIALS RESEARCH SOCIETY SYMPOSIUM PROCEEDINGS

Theodore M. Besmann, Bernard M. Gallois, and James W. Warren Apr. 1993 386 p Symposium held in Boston, MA, 4-6 Dec. 1991
(AF Proj. 2306)
(AD-A265072; AFOSR-93-0267TR) Avail: CASI HC A17/MF A04

The production of thin or thick films of metals or ceramics by chemical vapor deposition has often been achieved by the use of halide gas precursors. In certain cases, this choice was made purely for reasons of simplicity. Experience has subsequently shown, however, that this choice can give rise to significant changes in the nature and proportions of deposited phases. These are highly dependent upon the following: the value of the oxidiser:reducer ratio in the gas phase; the degree of metal oxidation in the halide considered; and possible competition between two reducing agents designed to reduce the halide. These factors, among others, strongly influence the thermochemistry of the deposition reaction. Their roles must therefore be clearly understood, interpreted and predicted by the thermochemical analysis. Based on examples relating to silicide, nitride, and boride deposits, an attempt will be made to determine sensitive parameters and deduce selection criteria. DTIC

PROCESSING AND PROPERTIES OF COATED HPZ FIBER REINFORCED GLASS-CERAMIC MATRIX COMPOSITES Final Report, May 1988 - Jan. 1993

John Brennan, William Allen, Philip McCluskey, and David Jarmon 31 Mar. 1993 124 p
(Contract F49620-88-C-0062)
(AD-A265177; R93-970104-2; AFOSR-93-0362TR) Avail: CASI HC A06/MF A02

The main objective of this program was to utilize fiber coatings to tailor, or 'engineer,' the chemistry and bonding characteristics of the fiber/matrix interface in glass-ceramic matrix composites reinforced with Dow Corning's polymer derived Si-N-C-O 'HPZ' fibers such that relatively weak bonding exists at the interface to allow matrix crack deflection to occur, thus increasing the toughness and damage tolerance of the composite, while at the same time maintaining the high temperature oxidative stability of the matrix/coating/fiber interfacial region. In addition, for this particular system which is inherently reactive, the fiber coating must also act as a barrier to interdiffusion and reaction. A secondary objective of this program is to investigate advanced composite processing methods other than the traditional hot-pressing, such as hot isostatic pressing (HIP) and glass matrix transfer molding into integrally woven fiber preforms. During the performance of this contract, the microstructure and properties of HPZ fibers, CVD/BN, and SiC/BN coatings on HPZ fibers and barium magnesium aluminosilicate (BMAS) glass-ceramic composites fabricated with these coated fibers were investigated. CERAMICS FORMED BY PYROLYSIS OF EITHER LINEAR OR THERMOSETTING CARBORANE (SILOXANE OR SILANE) ACETYLENE BASED PRECURSOR POLYMERS Patent Application
Leslie J. Hnderson, inventor (to Navy) and Teddy M. Keller, inventor (to Navy) 8 Feb. 1993 35 p
(AD-D015747; US-Patent-Appl-SN-014928; Navy-Case-75190) Avail: CASI HC A03/MF A01

This invention relates to a new class of novel ceramic materials that are formed from linear inorganic-organic hybrid polymers of varying molecular weight. These new ceramics are formed from oxidatively stable thermosetting polymers which, in turn, are formed from linear polymeric material having repeating units that contain at least one alkynl group for cross-linking purposes and at least one bis (silyl or siloxanyl) carboranyl group. The thermosetting polymers are converted into the novel ceramics, the subject of the present invention, at elevated temperatures. DTIC

CERAMIC ACTUATORS FOR SMART MATERIALS Final Report, 1 Jul. 1991 - 30 Jun. 1992
L. E. Cross 30 Jun. 1992 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1922)
(AD-A265664) Avail: CASI HC A03

In earlier studies a number of phase switching systems had been explored which permit the switching of large electric polarization and the associated high elastic strain. The question to be resolved was whether these large polarization values could be repeatedly switched without associated mechanical or electrical fatigue. Early fatigue was shown to be an electrode problem, and with care in electrode application, density control, grain size control, and field homogeneity it was shown that full switching lifetimes, with no fatigue of more than 10(exp 9) cycles, were achievable. In polymer-ceramic composite transducers, the 1:3 type connectivity is highly desirable. A new theoretical approach has been made to calculate the inhomogeneous stress profiles in both piezoceramic and polymer phases. The predictions have been tested using the MRL ultra-dilatometer and good agreement is shown between predicted and observed strain profiles. A new type of 1:3 composite making use of radially poled ceramic tubes has been explored and shown to offer unusually attractive possibilities for the control of piezoelectric, elastic, and electric impedance characteristics and to offer a vehicle for the new electrostrictive agile piezoelectrics. INTERFACIAL MODIFICATION THROUGH END GROUP COMPLEXATION IN POLYMER BLENDS Technical Report, 1992 - 1993
C. A. Fleischer, A. R. Morales, and J. T. Koberstein 4 Jun. 1993 35 p
(Contract N00014-91-J-1786)
(AD-A265887; TR-1) Avail: CASI HC A03/MF A01

The concept of interpolymer complexation is applied to develop a new method for interfacial modification of immiscible binary homopolymer blends. In this method, end-functional homopolymers terminated with acid and base groups are added to the blend to promote in situ end-complexation of the immiscible materials across the interface. The interpolymer complex that forms between acid and base groups creates a 'block-copolymer-like' structure that spans across the interface. Pendant drop tensiometry is applied to measure the interfacial tension reduction afforded by this complexation. The interfacial tension data show behavior similar to that observed for block copolymer addition to homopolymer blends. In difference to the behavior of block copolymers, however, the formation of interpolymer complexes is dependent on the equilibrium between associated and dissociated functional groups. That is, the ultimate plateau value for interfacial tension reduction is dependent on the functional group stoichiometry. A reaction model for end-complexation is developed including the effects of carboxylic acid dimerization in order to reproduce the interfacial reduction data. Fourier transform infrared spectroscopy is applied to determine the appropriate rate constants. Finally it is shown that the overall interfacial tension behavior is consistent with that predicted by current statistical thermodynamic theories developed for block copolymers. DTIC

DYNAMIC HIGH-PRESSURE SHOCK COMPACTION OF DIAMOND POWDERS Final Report, May 1991 - 25 May 1993
N. N. Thadhani, P. A. Persson, A. Grebe, V. S. Joshi, and T. J. Arhens 25 May 1993 86 p Prepared in cooperation with CalTech, Pasadena, CA
(Contract N00014-91-C-2173)
(AD-A266004; EMRTC-FR-93-12) Avail: CASI HC A05/MF A01

The present report summarizes investigations carried out on shock consolidation of diamond powders for fabrication of compacts for electronic substrate applications. Consolidation of various types of commercially available natural and synthetic diamond powders has been performed in this study. The type of diamond and morphology of the powder particles affects the consolidation mechanisms as well as the diamond compact characteristics. It is shown that with the use of appropriate particle size distribution, and therefore a high initial packing density, compacts with optimum physical characteristics crack-free and better than 90% of theoretical maximum density can be obtained. However, about 3-5% transformed graphite and extensive residual strain in the compacts has been detected, both of which severely limit the thermal conductivity. The work contained in this report provides an extensive series of experimental results and mechanistic studies discussing the consolidation behavior of diamond powders by the shock compression technique. A RELAXATION STUDY OF POLED NONLINEAR OPTICAL POLYMERS BY INFRARED REFLECTION-ABSORPTION SPECTROSCOPY Technical Report, 1 Jun. 1992 - 31 May 1993
J. I. Chen, S. Marturunkakul, Y. M. Chen, J. Kumar, and S. K. Tripathy 31 May 1993 24 p
(Contract N00014-90-J-1148)
(AD-A265797; TR-93-01) Avail: CASI HC A03/MF A01

The relaxation of poled nonlinear optical (NLO) chromophores in polymer films was characterized by infrared reflection-absorption spectroscopy. Both a guest-host system and a photocrosslinkable polymer system were investigated. Polymethylmethacrylate (PMMA) doped with either 2-methyl-4-nitroaniline (MNA) or 4(4'-nitrophenylazo) phenylamine (DO3) was studied. The photocrosslinkable polymer system, polyvinylcinnamate (PVCN) doped with xy-phenylazo-nitrobenzene (CNNB-R) was also investigated. Doped NLO active molecules were aligned using the corona poling technique. Infrared spectra as a function of time were used to monitor the relaxation behavior of the oriented dyes after poling. Relaxation of NLO molecules was followed at various characteristic vibrational frequencies. The relaxation of MNA was found to be faster than that of DO3. The NLO dye molecule, CNNB-R was covalently bonded to the host polymer and formed a three dimensional crosslinked network after ultraviolet (UV) irradiation. Relaxation of NLO molecules in pristine and UV treated samples were compared. The

UV light induced crosslinking provided better temporal stability of molecular alignment in this system. DTIC

THE 13C AND 15N SOLID-STATE NMR OF COPOLYMERS OF NYLON 6 AND 7: OBSERVATION OF A STABLE PSEUDOHEXAGONAL PHASE Technical Report, 1 Jun. 1992 - 31 May 1993

C. G. Johnson and L. J. Mathias 7 Jun. 1993 20 p
(Contract N00014-89-J-1225)
(AD-A265799; TR-54) Avail: CASI HC A03/MF A01

We have synthesized and characterized a series of nylon copolymers based on the even-odd A-B monomer combination, caprolactam, and enantholactam. The nylon 6-co-7 samples obtained were found to possess physical properties which directly correlate with copolymer composition. We have determined degrees and types of crystallinity for these materials using a combination of thermal, NMR, and X-ray measurements. The homopolymers each display highly ordered alpha-crystallites while the copolymers possess less-ordered domains that decrease in alpha-like characteristics down to the 1:1 copolymer which possesses a thermodynamically stable pseudohexagonal ordered phase. The 13C T1 values determined for the annealed 1:1 copolymer were shorter than those of crystalline regions of homopolymers, comparable to those observed for amorphous domains in melt quenched nylon 6 and nylon 7 homopolymers, and significantly longer than the values for precipitated and annealed 1:1 nylon 11-co-12 sample. DTIC

POLYMERS FOR MICROELECTRONICS Technical Report, Mar. 1992 - Jun. 1993

S. X. Cai, M. N. Wybourne, and J. F. Keana 10 Jun. 1993 11 p
(Contract N00014-92-J-1412)
(AD-A266036; UO-JFWK-MNW-02) Avail: CASI HC A03/MF A01

A comparative study of polystyrene (PS) with bis(perfluorophenyl) azides 1-2 and the corresponding non-fluorinated bisazides 3-4 as deep-UV resists is reported. Inclusion of as low as 1.2 wt-% of 1 in PS led to 70% retention of film thickness after photolysis and development. PS containing 2.4 wt-% of 1 is greater than 100 times more sensitive as a deep-UV negative resist than PS itself. The presence of 1 in PS also increased the contrast of the resist. On a molar basis, 1 was about 10 times as effective as non-fluorinated bisazide 3 in cross-linking PS while 2 was about 6 times as effective as 4. PS containing 2.4 wt-% of 1 was found to have a deep-UV sensitivity of 5-10 mJ/sq cm and resolution of about 0.5 micrometer. DTIC

SYNTHESIS AND POLYMERIZATION OF OLIGOMERIC MULTIPLE AROMATIC ETHER-CONTAINING PHTHALONITRILES Patent Application

Teddy M. Keller, inventor (to Navy) 18 Feb. 1993 29 p
(AD-D015729; US-Patent-Appl-SN-019373; Navy-Case-73258) Avail: CASI HC A03/MF A01

Oligomeric monomers are produced by reaction of a bisphenol compound with either a dihalobenzophenone or a (2,2) bis (4-halophenyl) hexafluoropropane and any other activated halogen containing aromatic compounds in the presence of a base and an appropriate solvent. The resulting oligomeric product, a dialkaline bisphenate terminated salt, is then reacted with 4-nitrophthalonitrile to form an oligomer-based phthalonitrile. These oligomers, in the presence or absence of a curing agent, may then be heated to form high temperature thermosetting polymers. These polymers can potentially be used as advanced materials for composites, as adhesives, and for microelectronic applications. DTIC

FRACTURE BEHAVIOR OF IONOMERS AND IONOMERIC BLENDS

Masanori Hara 27 Feb. 1993 3 p
(Contract DAAL03-89-K-0044)
(AD-A265379; ARO-25424.15-MS) Avail: CASI HC A01/MF A01

We have elucidated the deformation/fracture behavior of ionomers and correlated them to their microstructure. We have also found important molecular variables to achieve enhanced fracture properties of ionomers: high ion content above a critical value, divalent counterions, and excess neutralizing agent. We have elucidated the structural changes associated with the change of each molecular variable. Subsequently, we have produced unique blends made of small amounts of ionomers and large amounts of unmodified polymers. They show synergistic mechanical behavior, retention of transparency of the unmodified polymer, good processability, and excellent cost performance. We have elucidated the structural characteristics responsible for these behavior. Author (DTIC)

MOLECULAR PROPERTIES OF POLYMERIC MATERIALS FOR SPACE APPLICATIONS Final Report, period ending 15 Apr. 1992

Wynford L. Harries, Kristen T. Kern, and Phillip C. Stancil May 1992 13 p
(Contract NCC1-139)
(NASA-CR-194370; NAS 1.26:194370; ODU-TR-PTR-92-1) Avail: CASI HC A03/MF A01

This cooperative agreement was intended to investigate the effects of a space environment on the properties of polymeric materials. In addition, efforts have been made to understand and investigate environment simulation techniques and test methodology. The results identified the changes in the properties of six aerospace structural adhesives, three neat high polymers, and two fiber-reinforced polymers, as caused by exposure to four simulated space environmental conditions. Significant property changes occurred for several of the systems as a result of one or more of the exposures. A summary of the research follows a list of related publications and presentations. CASI

A melanin-like polymer was prepared by diazotizing luminol (5-amino-2,3-dihydro-1, 4-phthalazinedione) and 3-amino-L-tyrosine in a mixed water/dimethylsulfoxide solvent; this was followed by acetone precipitation and aging of the solid residue for a month (the polymer forms slowly in the solid residue). An aqueous solution containing 0.50 F NaOH, 0.0011 M luminol, 0.010 F potassium formate and the polymer at a concentration of 0.050 mg/mL was observed to undergo an instantaneous seven-fold increase of chemiluminescence when the solution was subjected to a 0.5 Watt/mL irradiation with 20 kHz acoustic energy. This sonochemiluminescent property suggests that earlier reports of strobes of luminescense induced by pulsed microwave irradiations of aqueous solutions of the polymer might have an origin in the microwave acoustic effect. Since the sonochemiluminescent effect is marked and easily detected, the polymer may be applicable as a dosimeter for studying acoustic effects in pulsed, high-powered microwave irradiations, especially where the target geometry is complex. Further insight into the observed properties will depend on a characterization of the structure of the polymer, which is currently not known. Attempts at a structural characterization have been hampered thus far by a lack of suitable polymer fragments, i.e., a reliable means for fragmenting the polymer or limiting its DPn has not been found. PREPARATION OF STABLE PHOTOPATTERNABLE POLYMERIC MATERIALS FOR NON-LINEAR OPTICS
Jean M. Frechet, Jody E. Beecher, Tony Durst, and Adelheid Godt 12 May 1993 14 p
(Contract N00014-91-J-1338)
(AD-A265359; TR-12) Avail: CASI HC A03/MF A01

Several new functionalized chromophores have been prepared and tested in the preparation of optically stable, photopatternable, NLO polymers for second harmonic generation at the diode laser wavelength of 820 nm. In particular, chromophores containing the sulfonamide or sulfonate ester functionalities have been found to be extremely versatile as they allow attachment of a polymerizable group at the electron-poor end of NLO chromophores. The results of model studies confirm that the sulfonamide groups do not have a deleterious effect on NLO properties. Several new monomers containing 4-alkoxy-4'- sulfonamido-stilbene moieties have been prepared. The 4-alkoxy end of the chromophore is designed to allow its incorporation into a linear polymer backbone. The sulfonamido end of the chromophore has a polymerizable double bond that can be photocrosslinked after poling of the chromophores. As it is extremely important to carry out the photopatterning step without affecting the NLO chromophore or introducing any color into the imaged polymer, novel photoinitiators were tested and found to be suitable. The radiation induced photo-patterning step can be done without causing isomerization of the stilbene chromophores, or introducing any color into the patterned coating. DTIC

PHOTOGENERATED BASE IN POLYMER IMAGING. SYNTHESIS AND PHOTOPATTERNING OF POLY(2-CYANO-2-(P-VINYLPHENYL) BUTANOIC ACID)
Man-Kit Leung, Jean M. Frechet, James F. Cameron, and C. G. Willson 12 May 1993 14 p
(Contract N00014-91-J-1338)
(AD-A265288; TR-10-ONR) Avail: CASI HC A03/MF A01

Since the concept of chemical amplification was first introduced by us more that twelve years ago, a number of new resists based on acid-catalyzed thermolysis have been developed and commercialized. This report describes the first chemically amplified resist operating through photogenerated base. The concept is demonstrated with poly(2-cyano-2-(p-vinylphenyl) butanoic acid) which decarboxylates readily under basic conditions. A resist system consisting of this polymer and an amine photogenerator bis(2,6-dinitrobenzyloxy) carbonylhexan-1,6-diamine has been formulated and tested in microlithography. The sensitivity of this resist is extremely high (1.4 mJ/sq cm) with a very high contrast of 13.7. This very high sensitivity confirms that chemical amplification is achieved as the photogenerated base is not consumed in the overall decarboxylation process. The mechanistic insights gained from the study of the decarboxylation process may be used in the design of other resists involving more readily accessible polymers. DTIC

Ion Beam Sputtered (IBS) coatings offer some distinct advantages over electron beam deposited (e-beam) coatings, namely environmental stability and extremely low total losses. Initial IBS coatings had excessive stress and low laser damage thresholds. For these reasons, a study was initiated to examine potential laser damage thresholds and stress of IBS coatings. A material study was conducted of IBS coatings produced in industry, and a variety of design techniques were explored to increase laser damage thresholds. A post annealing process and backside coatings were developed to reduce the coating stress. DOE

PREDICTION OF ALUMINA PENETRATION
D. A. Mandell Feb. 1993 30 p
(Contract W-7405-eng-36)
(DE93-014017; LA-12520) Avail: CASI HC A03/MF A01

The MESA hydrocode was used to predict two-dimensional tests of L/D 10 and L/D 15 tungsten rods impacting AD 90 alumina with a steel backing. The residual penetration into the steel is the measured quantity in these experiments conducted at the Southwest Research Institute (SWR). The interface velocity as a function of time between an alumina target and a lithium fluoride window, impacted by an alumina disk at velocities between 544 m/s and 2329 m/s, was also predicted. These one-dimensional flyer plate experiments were conducted at Sandia National Laboratories using Coors AD 995 alumina. The material strength and fracture models are important in the prediction of ceramic experiments. The models used in these predictions are discussed. The penetrations in the two-dimensional tests were predicted to 11.4 percent or better. In five of the six experiments, the predicted penetration depth was deeper than the measured value. This trend is expected since the calculation is based on ideal conditions. The results show that good agreement between the 1-D flyer plate data and the MESA predictions exists at the lower impact velocities, but the maximum velocity is overpredicted as the flyer plate velocity increases. At a flyer plate velocity of 2329 m/s the code overpredicted the data by 12.3 percent. DOE

SENSITIVITIES OF CALCULATED RESIDUAL STRESS TO SEPARATION DISTANCES OF TWO SIMULTANEOUS EVENTS
J. T. Rambo and W. C. Moss Feb. 1992 20 p Presented at the 6th Symposium on Containment of Underground Nuclear Explosions, Reno, NV, 24-26 Sep. 1991
(Contract W-7405-eng-48)
(DE92-019571; UCRL-JC-109645; CONF-9109114-12) Avail: CASI HC A03/MF A01 (US Sales Only)

LLNL has developed calculational capabilities to model simultaneous explosions of different yields with DYNA2D. Past experimental experience suggests that double events are contained when the work points are separated by no less than twice the sum of the final radii of the two cavities with the higher yield device buried at a safe depth and above the lower yield device. In the past, this non-optimal use of the drill hole was chosen to ensure safe containment and to provide cost savings. Although additional savings can be realized by placing the lower yield device above the higher yield device, there is no really relevant experimental experience. Given current and projected funding levels for the nuclear testing program, study (calculationally) of the feasibility of a low-over-high emplacement could make possible significant savings. In this study we examine the sensitivity of the residual stress field to work point separation for a one kiloton device placed above a ten kiloton device. The geometry is cylindrically symmetric. Work point separations were varied between 50 and 300 m. The depth of burial for the upper device was fixed at 270 m so that overburden would not be a sensitivity factor in the residual stress calculation. Results show that unanticipated weaknesses in the residual stress of the lower yield device occur at some work point separations. DOE

VEHICULAR FLEET OPERATION ON NATURAL GAS AND PROPANE: AN OVERVIEW Final Report
Dean B. Taylor, Hani Mahmassani, and Mark A. Euritt Nov. 1992 116 p See also PB92-218049 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-194603; CTR-3-4-90/2-983-5F; TX-93+983-5F) Avail: CASI HC A06

The report attempts to contribute to the timely area of alternative vehicular fuels. It addresses the analysis of fleet operation on alternative fuels, specifically compressed natural gas (CNG) and propane, in terms of both fleet economics and societal impacts. Comprehensive information on engine technology, fueling infrastructure design, and societal impacts are presented. An evaluation framework useful for decisions between any vehicular fuels is developed. The comprehensive fleet cost-effectiveness analysis framework used in previous Project 983 reports is discussed in great detail. This framework/model is flexible enough to allow substantial sensitivity and scenario analysis. The model is used to perform sample analyses of both fleet economic and societal impacts. NTIS

COMBUSTION-INDUCED CRACK PROPAGATION PROCESS IN A SOLID-PROPELLANT CRACK CAVITY Ph.D. Thesis
Yeu-Cherng Lu 1992 155 p
Avail: Univ. Microfilms Order No. DA9311683

The presence of flaws in a burning solid-propellant rocket motor grain could potentially cause anomalous burning leading to unexpectedly high pressure and subsequent failure of the motor. Present understanding of the combustion and fracture processes in such flaws is limited by the difficulty of instrumenting a full-scale burning grain. Thus, the problem was attacked by taking measurement in a labscale fracture/combustion test rig as well as by developing a coupled finite-element/finite-difference computer code. Emphasis was placed on the investigation of the effects of propellant type, pressurization rate, and boundary confinement on combustion-induced crack propagation in the damaged zone of a propellant grain. Both crack and debond samples were tested. Two types of propellant were studied: AP/PBAN/Al composite and polyester-based high-elongation propellants. A windowed test chamber was designed and fabricated for use in crack and debond test runs. Data acquisition systems include high-speed cameras and pressure transducers. A theoretical model was established for simulating crack combustion process in solid propellants. The interrelated structural deformation and combustion process were simulated by integrating the following analyses: (1) transient, one-dimensional mass, momentum, and energy conservation equations for the gas phase; (2) a transient, one-dimensional heat conduction equation for the solid phase; (3) stress and strain calculations for a two-dimensional, linear viscoelastic, homogeneous, isotropic, thermorheologically simple solid propellant; and (4) fracture analysis for the propellant crack under dynamic pressure loading. The gas- and solid-phase governing equations were solved numerically using a finite differencing technique. Stress and strain calculations were performed with a commercially available finite element code (ANSYS). Quasi-elastic approximation was used to simplify the viscoelastic constitutive equations. J-integral was calculated for the determination of fracture initiation. A useful correlation for crack propagation speed was obtained by combining the information of experimentally observed crack speed and numerically calculated J-integral at different pressurization rates. Reasonably good agreement of crack contour and crack propagation speed between experimental and theoretical results was obtained. Dissert. Abstr.

BUSINESS FLEET REFUELING ASSESSMENT Final Report, Mar. - Nov. 1992
A. Chaudier Jan. 1993 73 p
(Contract GRI-5092-810-2365)
(PB93-189892; GRI-93/0026) Avail: CASI HC A04/MF A01

The report investigates refueling characteristics and capabilities for the light-duty market sector, particularly business automobile fleets. It develops a profile of the characteristics of light-duty and automobile business fleets in 22 designated non-attainment areas, as well as Pittsburgh and Salt Lake City. Reliable data on these subjects will enable better analysis of the market potential for natural gas in the surveyed areas. NTIS

ENERGY TRANSFER DYNAMICS AND IMPACT SENSITIVITY
L. E. Fried and A. J. Ruggiero Dec. 1992 8 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract W-7405-eng-48)
(DE93-009551; UCRL-JC-111995; CONF-921101-101) Avail: CASI HC A02/MF A01

In this paper we focus on the relation between impact sensitivity and energy transfer rates. When a crystal receives an impact, low frequency lattice vibrations (called phonons) are excited. Typical phonon frequencies are 0-200 cm(exp -1). This energy must then be converted to vibron frequencies (1000-2000 cm(exp -1)) before bond breaking can occur. We derive a simple formula for the energy transfer rate in terms of the density of vibrational states and the vibron-phonon coupling. We are able to estimate the phonon upconversion rate in widely varying energetic materials such as TATB, HMX, and Pb styphnate by examining existing inelastic neutron scattering data. We find that the estimated energy transfer rates in pure unreacted material are strongly correlated with impact sensitivity. DOE

SUBMARINE INTERNAL WAVES
E. O. Tuck (Adelaide Univ., Australia.) Jan. 1993 64 p
(MRL-GD-0049; AR-008-256) Avail: CASI HC A04/MF A01

Details are provided of research directed towards the development of the computer program WAKE for predicting the internal waves produced by the passage of a submarine in a density stratified ocean. The research was undertaken within DSTO during the period Feb.-Mar. 1992. The report takes the form of a series of appendices (presented in chronological order), which provide a record of the progress of the research during that period. Results are presented which indicate that a representative submarine produces internal waves which have a velocity magnitude of about one millimeter per second. Author (revised)

ADVANCED DIAGNOSTICS FOR IN SITU MEASUREMENT OF PARTICLE FORMATION AND DEPOSITION IN THERMALLY STRESSED JET FUELS

T. J. OHern, W. M. Trott, S. J. Martin, and E. A. Klavetter 1993 12 p Presented at the 31st AIAA Aerospace Sciences Meeting, Reno, NV, 11-14 Jan. 1993 Previously announced in IAA as A93-23045
(Contract DE-AC04-76DP-00789)
(DE93-009798; SAND-92-1168C; CONF-930108-6; AIAA Paper 93-0363)
Avail: CASI HC A03/MF A01

Two techniques have been developed and applied for in situ monitoring of the processes involved in thermal degradation and solids deposition when several different aviation fuels are thermally stressed. Photon correlation spectroscopy is a dynamic light scattering technique that has proven to be a valuable tool for both real-time and post-test analysis of thermally stressed jet fuels. In situ measurements of post-stressed fuels have shown that significant particle formation can occur at temperatures as low as 120 C, and that relatively large particles (greater than 200 nm mean hydrodynamic diameter) are formed at temperatures less than 200 C. Particle size tends to increase with increasing stress temperature over the range 125-180 C, with substantial changes in the mean particle size occurring over ranges of only 10-20 C. Real-time measurements indicate that the mean particle diameter increases with increased exposure time at fixed temperature. An induction time is also evident in the real-time data, as an increasingly shorter exposure time is needed for particles to form in detectable size and concentration as the stress temperature is increased. The particle diameters measured post-test, when the fuel has cooled to room temperature, are larger than those measured at elevated temperatures, demonstrating the need for real-time measurements. A complementary experimental system using a quartz crystal microbalance has proven valuable for in situ determination of mass deposition rates during thermal stress tests. These data can be used to determine such kinetic factors as the global activation energies for the tested fuels and for quantitative evaluation of fuel thermal stability. DOE

PREPRINTS OF THE 13TH HYDROGEN ENERGY SYSTEM SYMPOSIUM
Masaru Hiruma, Hiromasa Hashimoto (National Space Development Agency, Ibaraki, Japan.), and Yasuharu Hosono 17 Nov. 1992 56 p Symposium held in Tokyo, Japan, 17 Nov. 1992
(DE93-781115; ETDE/JP-mf-93781115) Avail: CASI HC A04/MF A01

Twelve preprints, which were given originally at the 13th Hydrogen Energy System Symposium, are presented. The preprints cover the following topics: a study on a hydrogen engine with direct injection before TDC; a study on the combustion of hydrogen jet in hydrogen engine; tests of a hydrogen-oxygen combusted gas turbine with inert-gas recirculation; flow analysis of a scramjet engine combustor; a study of the structure of a liquid hydrogen pump;the fuel vessel of an LNG vehicle; magnetic field effects on metal hydride electrode potential; absorbing-desorbing characterization of Ti-V-Fe alloy system; the effects of measurement condition and method on cyclic hydriding and dehydriding property of hydrogen storage alloys; studies on the match between the PV array and S.P.E. electrolyzer; cost estimate of photovoltaic hydrogen production; and a catalyst study on liquid-phase dehydrogenation of cyclohexane for thermo-regenerative fuel cell. A NOVEL TEST METHOD FOR FUEL THERMAL STABILITY Final Report, 13 Apr. 1992 - 13 Jan. 1993
Michael A. Serio, David S. Pines, Erik Kroo, Kim S. Knight, and Peter R. Solomon Feb. 1993 84 p
(Contract F33615-92-C-2213)
(AD-A265853; AFR-526021; WL-TR-93-2032) Avail: CASI HC A05/MF A01

The object of this work was to demonstrate that an FT-IR fiber optic probe and a quartz crystal microbalance (QCM) probe could be used to measure deposit formation from thermal stressing of jet fuels in a high-temperature, high pressure flow system. These probes were designed, constructed, and tested in an existing Fuel Stability Test System (FSTS) which had an FT-IR Attenuated Total Reflectance (ATR) circle cell monitoring the stressed fuel after cooling to ambient temperature. Shell Jet A and Sun Jet A-1 fuel were tested. It was demonstrated that both the FT-IR fiber optic probe and the QCM probe could successfully differentiate between a 'stable' and an 'unstable' fuel. The results from the QCM probe tests indicate that the drop in frequency for this particular probe results from viscosity dampening and not the mass of the film. The changes in the bulk fuel composition from thermal stressing were measured with the ATR circle cell and were found to be significantly different from the changes in the deposit layer composition measured by the fiber-optic probe. ADVANCED THERMALLY STABLE COAL-DERIVED JET FUELS: COMPOSITIONAL FACTORS AFFECTING THERMAL DEGRADATION OF JET FUELS Annual Report, 1 Aug. 1991 - 31 Jul. 1992
C. Song, S. Eser, H. H. Schobert, P. G. Hatcher, and M. M. Coleman Dec. 1992 177 p
(Contract MIPR-FY1455-91N-0638; AF Proj. 3048)
(AD-A265842; WL-TR-93-2007) Avail: CASI HC A09/MF A02

This project focuses on the compositional factors affecting the high temperature thermal stability of coal-derived and petroleum-based jet fuels in the pyrolytic regime. Thermal stability refers to the resistance of fuel to chemical decomposition at high temperatures to cause the solid deposition and liquid depletion. There are four broad objectives in this project, and the research work is divided into four tasks. The first task clarifies the chemistry of fuel degradation and mechanisms of solid formation, identifies thermally stable classes of hydrocarbon compounds, and provides information for enhancing intrinsic stability of jet fuels. The second task involves characterization of the solids including deposits, sediments, and gums produced from fuels and model compounds at high temperatures. The third task is to explore the means to enhance the thermal stability of fuels by examining the effects of various additives. The fourth task is a newly initiated exploratory study on conversion of coals to thermally stable jet fuels. DTIC

DISTRIBUTED COMBUSTION IN SOLID PROPELLANTS Final Report, 1 Feb. 1991 - 1 Feb. 1992
M. W. Beckstead and K. P. Brooks Mar. 1993 58 p
(Grant AF-AFOSR-0152-91)
(AD-A265727; AFOSR-93-0401TR) Avail: CASI HC A04/MF A01

This report summarizes work on a research program to quantify the effect of distributed combustion of metal particles in a Rijke burner. Under a previous contract, experimental data were obtained with the Rijke burner, and a mathematical model of the burner was developed. To improve the model, the McIntosh flame model, based on large activation energy asymptotics, has been coupled to the acoustic model. Results have been compared to experimental data showing that the McIntosh transfer function is an improvement over previous models. Law's model of aluminum combustion has been modified to include the effects of multiple oxidizers and their products, oxide accumulation on the surface of the burning aluminum particle, and convection. There are no adjustable parameters in the improved aluminum combustion model, and both transport and thermodynamic properties are calculated internally. Results indicate that the modified model compares more favorably to experimental data than a simple liquid droplet model. The aluminum combustion model has also been coupled to the Rijke acoustic model. Calculations show a sensitivity to the size of the region of influence surrounding a particle and to the time lag between the particle response and the acoustic pressure. The results show reasonable agreement with available data for aluminum particles burning in the Rijke burner. DTIC

THE FORMATION AND BREAKAGE OF LIQUID BRIDGES UNDER MICROGRAVITY
John F. Padday *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 41-49 (For primary document see N94-10070 01-29)

The formation and breakage of liquid bridges under microgravity was analyzed experimentally from data obtained in parabolic flight, and it is shown that all such formation and breakages take place in at least two stages. With respect to breakage, the first stage, the bifurcation process, is shown to be slow and is driven slowly by diminution in surface free energy. The energy is, however, sufficiently large to increase the capillary pressure inside the bridge. The second stage may follow one of two paths depending on the capillary number of the liquid. At low capillary number, the neck of the bridge forms a rod of liquid which then breaks at each end to form a satellite drop, while the two liquid caps recoil under inertial forces. At high capillary number, the rod diameter decreases successively until it becomes threadlike and finally microscopic. Under these conditions no visible satellite drop is formed and no recoil occurs. Some experiments were performed which followed the merging of two spherical caps of liquid to form a stable unified zone. The process of merging is shown to require a small capillary pressure to bring the surface molecules into contact. Thereafter, the equilibrium shape is reached only after minimum area is reached. Again, liquids with high capillary number reach equilibrium quiescently whereas those with a low capillary number undergo traumatic union. When the two caps are composed of immiscible liquids the merging process is not as traumatic but is greatly slowed down as the new liquid-liquid interface is generated. The breakage follows the same pattern as with a single liquid, but the liquid of lowest surface tension is the phase in which breakage occurs. ESA

The steady small amplitude thermocapillary driven convection and deformation of the free surface in a floating zone held by capillary forces between two circular concentric solids is experimentally analyzed when the temperature is not constant along the interface and the gravitational effects can be neglected. The technique of diagnosis implemented in order to analyze the induced Marangoni convection is presented. The aim of these combined techniques is to determine the interface deformation and the velocity field inside a floationg zone, heated from above and cooled from below, at the same time. An experimental set up was devised and a number of experiments with different liquids and slenderness, using millimetric floating zones in order to simulate reduced gravity conditions, were carried out. Results of these experiments related both in the interface deformation and in the velocity field are presented. The shape of the free surface is determined using a high contrasted illumination of the float zone and acquiring and analyzing the image in real time. The particle displacement tracking technique is used to estimate the induced velocity field inside the float zone. ESA

Experiments which investigated the occurrence of Marangoni Convection (MC) in GaAs Floating Zones (FZ) are presented. Previous results obtained in TEXUS flights, terrestrial crystal growth (with small diameters), and numerical calculations showed that the Marangoni convection causes unsteady flow conditions in the melt during crystal growth. As a result, the FZ grown GaAs crystals contain doping striations. The possibility of establishing steady growth conditions using magnetic fields was consequently investigated. A series of results of terrestrial FZ GaAs experiments under the influence of magnetic fields is presented. It is shown that the formation of striations due to unsteady MC can be avoided during FZ growth of (d approximately equal to 6 mm) GaAs crystals by using axial or transverse magnetic fields of a certain strength. The values of the critical induction, B(sup c) are in the range of B(sup C) is approximately 120 mT (h/d = 1.0) and B(sup C) is approximately 140 mT (h/d = 1.2). The experimental set up of the permanent pole magnet device to be used in the mirror furnace Parelli during the D2 mission is shown. Results of a numerical modeling of the MC under the conditions of these inhomogeneous field conditions are presented. ESA

The complete set of nonlinear equations which govern the motion of an inviscid liquid column is studied by means of an integral formulation of the problem. Viscous effects were neglected, and the liquid column was assumed to be rotationally symmetric, but otherwise no restrictions were imposed. This integral formulation is particularly advantageous in an axisymmetric configuration, since it yields a one dimensional problem with unknowns restricted to the free boundary. The evolution of the capillary surface can be traced beyond the point at which the liquid column breaks. ESA

DIELECTRIC LIQUID BRIDGE STABILIZATION IN MICROGRAVITY BY MEANS OF ELECTRIC FIELDS
Antonio Castellanos, Antonio Ramos, and Francois Gonzalez *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 67-71 (For primary document see N94-10070 01-29)
(Contract DGICYT-PB-90-0905)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The role of the different parameters affecting the stability of dielectric liquid bridges subjected to electric fields is presented. Two approaches were used to solve the governing electromechanical equations. First, the Lyapunov-Schmidt reduction was applied to obtain the local bifurcation nature and stability criteria of cylinders and quasicylinders (with residual gravity). Secondly, the Galerkin/finite element method was implemented to extend this study for a wider range of parameters for nonrotating bridges. The differences in electrical permittivites, the volume of the zone, and gravitational and centrifugal force effects upon the critical slenderness as a function of the applied electric field were taken into account. Results show that the electric field has a stabilizing effect somewhat similar to the inverse of the slenderness. ESA

INSTABILITY OF THERMOCAPILLARY CONVECTION IN FLOATING ZONES c76

G. Chen and Bernard Roux *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 73-78 Sponsored by CNES (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Bifurcation theory combined with the finite difference method is applied to investigate the instability of thermocapillary convection in a model of the floating zone crystal growth process. Both axisymmetric (n = 0) and nonaxisymmetric (n greater than or equal to 1) disturbances for an axisymmeric steady state of thermocapillary convection in a floating zone of O(1) aspect ratio (length/radius) are considered. The critical Marangoni number, the associated oscillatory frequency and the convective flow at the bifurcation are predicted by solving an extended system of steady equations. The critical values of the Marangoni number for the bifurcation from the steady thermocapillary convection to periodic one in time are found very dependent on the Prandtl number of the fluid and the aspect ratio of the floating zone. The variation with these parameters of the threshold for oscillations is obtained by continuation method. ESA

THERMOCAPILLARY INSTABILITIES IN CYLINDRICAL LIQUID BRIDGES: MECHANISMS AND TRANSITION BOUNDARIES c34

Hendrik C. Kuhlmann *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 79-83 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The stability of steady two dimensional thermocapillary flow in a differentially heated cylindrical liquid bridge of unit aspect ratio is investigated numerically. The basic state is calculated by a Galerkin tau method and the linear stability equations are solved by Galerkin collocation tau. For small Prandtl numbers a new symmetry breaking hydrodynamic instability is found, which is stationary, whereas the supercritical flow for larger Prandtl numbers is identified as a superposition of two hydrothermal waves. In both cases the azimuthal wave number of the critical mode is one. Heat loss of the liquid bridge stabilizes or destabilizes the base state depending on the Prandtl number. ESA

STABILITY OF LIQUID BRIDGES BETWEEN PARALLEL PLATES c34

Dieter Langbein *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 85-93 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The shape and stability of liquid bridges between parallel plates is investigated. The axisymmetric solutions of the capillary equation under microgravity conditions are nodoids, catenoids, and unduloids. The unduloids fit between parallel plates; if the slope at their inflection point falls short of the contact angle of the liquid with the two plates. Depending on whether the inflection points lie inside or outside the plates, several families of axisymmetric solutions arise. In the case of equal contact angles at both plates, the unduloids become unstable if the slope at the inflection point equals the contact angle. A second stability limit arises from the minimum volume conditions, that is, if two surface shapes enclosing the same liquid volume show up within a family of solutions of the capillary equation. Both kinds of instabilities coincide, if the contact angle equals 31.15 deg. If the contact angles at the two plates differ, the families of unduloids split up accordingly. Their stability is limited by the minimum volume condition. Respective stability diagrams are presented. Another well known asymmetry between the two plates arises from gravity. The stability limits in dependence on Bond number and liquid volume are also given. ESA

TRANSIENT THREE-DIMENSIONAL NUMERICAL SIMULATION OF MARANGONI FLOW IN A LIQUID COLUMN UNDER MICROGRAVITY c34

Johannes Straub and Rudi Marek *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 95-101 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The interaction of buoyancy and Marangoni flow in a vertical cylindrical floating zone of aspect ratio 1 with an adiabatic free lateral surface and isothermal top and bottom walls is studied numerically in a transient three dimensional simulation under zero, micro, and Earth gravity conditions. In zero gravity, a rotationally symmetric toroidal flow pattern evolves. The flow mode and the corresponding isotherms remain qualitatively unchanged in all gravity environments. Although natural convection itself forms a single roll, no significant distortion of the symmetric toroidal flow mode occurs, when buoyancy and surface tension driven flows interact. In this study, not only the flow field but also the heat transfer in the liquid bridge is investigated. The enhancement of the steady state heat transfer is examined for Marangoni and buoyancy convection acting in the same or in the opposite direction. The dependence of the overall heat transfer rate on the strength of the thermocapillary convection is established. In a range of Ma greater than or equal to 1 and less than or equal to 10(exp 7), no transition from the steady thermocapillary flow to stable oscillations is observed. ESA

Computer simulation of heat transfer and fluid flow was conducted to study the effect of rotation on microgravity floating zone crystal growth. The feed rod and the growing crystal were counterrotated at different, as well as the same, speeds ranging from 0 to 400 rpm. A high Prandtl number material NaNO3 (Pr = 9.12) and a low Prandtl number material Si (Pr = 0.01) were examined. The effect of rotation on the convection pattern in the melt and the shapes of the melt/solid interfaces was studied. It was found that rotation helps reduce thermocapillary convection and control the growth front shape very effectively in the case of NaNO3 but less so in Si. ESA

MARANGONI AND BUOYANT CONVECTIONS IN ZONE MELTING OF GaAs WITH LIQUID ENCAPSULATION c76

Jing Li (Aix-Marseilles Univ., France.) and M. Ziad Saghir *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 109-113 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Buoyant and thermocapillary flow in liquid bridges of GaAs melt and its encapsulant B2O3 are studied numerically. Half zone configurations are considered. The influence of buoyant flow on velocity and temperature distributions in the melt as well as in the encapsulant are studied. It is observed that the interfacial deformation is mainly caused by the hydrostatic pressure, however, with the increase of temperature difference, the dynamic effect can become strong enough to totally reverse the deformation of the interface when the bridges is heated at the top. The presence of encapsulant decreases significantly the thermocapillary convection in the melt. ESA

COUPLED THERMOVIBRATIONAL AND THERMOCAPILLARY CONVECTION IN LIQUID BRIDGE (FLOATING ZONE SYSTEM) c76

Grigory Z. Gershuni, Tatiana P. Lyubimova (Academy of Sciences, USSR, Perm.), D. V. Lyubimov (Academy of Sciences, USSR, Perm.), and Bernard Roux (Aix-Marseilles Univ., France.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 117-122 Sponsored by Academy of Sciences, Perm, Russia, and CNES (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Numerical simulation of time averaged thermovibrational convection, with or without thermocapillary effect, in a wide range of vibrational Rayleigh number, is addressed. The aim was to use axial vibration to damp thermocapillary convection and improve the crystal growth in the floating zone in weightlessness conditions. The numerical simulation showed that the vibration effect induces a flow that tends to make the isotherms perpendicular to vibration direction. The present results show that the thermocapillary flow is strongly reduced by the effect of axial vibrations. Thus, axial vibration appears to be a very effective way to dynamically control the convection in melts during crystal growth by floating zone techniques. Furthermore, it was shown that the efficiency of this dynamic control should be quite general for any other crystal growth technique, if the direction of vibration is perpendicular to the crystallization front. EFFECTS OF AXIAL AND CENTRIFUGAL FORCES ON THE STABILITY OF LIQUID BRIDGES **c34**

I. Martinez, J. M. Perales, and M. Gomez *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 123-130 Sponsored by Comision Interministerial de Ciencia y Tecnologia, Spain (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The equilibrium and stability equations for liquid bridges are well known, but they are nonlinear and it is difficult to guess real behavior, such as the sensitivity of the shape to axial and rotational forces (measured by Bond and Weber numbers, respectively) or to the geometry of the solid supports that support the bridge. A parametric study by numerical methods of the different effects and the analytical solutions at the bifurcation points in the stability diagrams is presented. The well known shooting method to numerically compute equilibrium shapes of liquid bridges, and their stability limits, is applied to a five parameter case, when different disc sizes (measured by H), bridge lengths (Lr), liquid volumes (Vr), residual axial acceleration (Bo), and solid body centrifugation (We) are contemplated. The bundle of diagrams presented give an idea of the complexities of such a multiparametric analysis and may help in further research to delimitate other forms of instability. The numerical results were used to check the validity of several analytical asymptotic expressions, with perfect agreement over the range of interest (long liquid bridges), but these models only take into consideration the subset (Lr, Vr = 1, H = 0, Bo, We) of the five parameter family. These results will be of great help to plan future space experiments on liquid columns and floating zones in space and in particular will show a method to easily measure very weak residual forces in microgravity platforms. LIQUID BRIDGES AND FLOATING ZONES **c34**

I. Martinez and A. Croell (Freiburg Univ., Germany.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 135-142 Sponsored by Comission Interministerial de Ciencia y Tecnologia, Spain (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Fluid science research in float zones, and more specifically on the mechanical stability of the liquid bridge model, is addressed. A liquid bridge spanning between two sharply edged coaxial solids represents a fluid interface configuration of the highest interest, both to basic fluid science and to materials science, particularly as a model of the molten bridge in the floating zone technique of crystal growth and high melting point refining. The float zone process is described, and differences between liquid bridges and float zones are given with regard to statics, dynamics, convection, diffusion, phase changes, electric and magnetic effects, and reactive processes. The conditions under which the liquid bridge model may be applied to real float zone processes are analyzed in detail. The application of this model to the real processing of silicon rods is presented. ESA

A review of the hydrodynamic instabilities observed on Earth during the evaporation of various liquids under constraint, for a plane surface or for drops evaporating in another immiscible liquid, is given. The constraints used are mainly an overheating of the liquid above the equilibrium temperature corresponding to the vapor pressure or a constraint of depression under the equilibrium pressure corresponding to the temperature of the liquid. On the basis of the theoretical analysis of the stability of the evaporating systems, the complexity of the coupling between volume (Rayleigh-Benard) instability and surface instabilies (Marangoni and Hickman instability) is highlighted. The role of gravity on these couplings is discussed through the dimensionless parameters of the problem. ESA

Results of the application of the PC based COMGA (Convection in Microgravity) code for numerical simulation of fluid dynamic experiments are presented. The global system which is called TOLS (Telescience On Line numerical Simulator) and which consists of hardware and software tools that simulate the process in real time and provide all the information to help the experimenter take appropriate decisions during the course of experiments is described. An example of a microgravity experiment on Marangoni convection in axisymmetric liquid bridge is used for calculations. The possibilities of calculation in real time are shown and discussed. It was shown that the PC-TOLS system COMGA is able to model regimes of Marangoni convection for telescience floating zone experiment conditions.

Modifications of COMGA system were carried out to accelerate the program and to use Intel-i860, and to change boundary conditions according to experimental data. A new improved version of COMGA for telescience real time calculation can qualitatively predict unsteady axisymmetrical Marangoni convection for floating zone experiments. It is necessary to introduce appropriate schemes in order to control numerical diffusion and to ensure accuracy of the computed values. It is suggested that the next versions of the simulator should allow input from the experiment of not only the boundary condition but also the measured temperature and velocity field. ESA

MODEL OF CONVECTIVE MOTION UNDER LOW GRAVITY

V. V. Pukhnachov *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 157-160 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

It is shown that the classic model of Oberbeck-Boussinesq is not applicable for the description of a liquid motion at very low gravity. Another model which is adequate to the investigated phenomenon is proposed. It is assumed that: the liquid density depends only on its temperature; the potential energy of liquid in the field of gravity is essentially less than its inner energy; the dissipation of the kinetic liquid energy during the motion is negligible; and the dynamic coefficient of liquid viscosity, the thermoconductivity coefficient and the heat capacity of liquid as well as their relation are constant. Magnetohydrodynamic equations were applied in three different commonly used approximations to a model system of a zone melting technique. Magnetic fields (B fields) can be used under microgravity conditions in order to suppress unsteady thermocapillary (Marangoni) convection and the disturbances occurring from steady as well as unsteady (g jitter) residual accelerations. A numerical modeling which is as close to reality as possible would be a valuable help for predicting experimental results and in designing the experiments. In the literature there are different approximations used to describe the magnetohydrodynamic interaction. The results of three commonly used approximations of a three dimensional numerical simulation of flow configurations and their time dependence are presented. The simulations were carried out for a terrestrial g level in order to compare them with experimental results published in an earlier paper. ESA

SURFACE-TENSION DRIVEN CONVECTION IN FINITE-SIZE CONTAINERS

G. Lebon (Louvain Univ., Belgium.) and Pierre C. Dauby *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 165-168 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

When a thin layer of fluid is heated from below and placed in a microgravity environment, surface tension effect is the single motor of convective instability (Marangoni effect). Although several works have been devoted to this subject, most of them concern fluid layers with lateral dimensions very much larger than their thickness. In the present note, this constraint is removed and finite size containers are considered. The critical Marangoni number and the critical wave number are calculated in the case of rectagular boxes. The influence of the dimensions of the boxes on the onset of convection is analyzed. The privileged planform is also determined. The numerical procedure is based on a variational principle. ESA

GAS-LIQUID JETS UNDER REDUCED GRAVITY CONDITIONS

Olaf Pamperin and Hans J. Rath *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 169-172 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Experimental drafts for the investigation of the behavior of gas-liquid jets under microgravity conditions and a conception of a facility to use inside the capsule of the drop tower Bremen are presented. Gas-liquid jets are very important subjects of fluid dynamic science with many applications in nature and industrial technique. In many cases of two phase flow it is possible to simulate the behavior of immiscible fluids with the help of gas-liquid systems, for example. The disturbance free investigation of two phase jets described by low inertial velocity and by clear density difference between the jet components, is almost impossible under normal gravity conditions. To realize gas-liquid jets without any disturbances and phase separating phenomena affected by convective mass transport a microgravity environment allows interesting experiments. Furthermore, surface tension can be observed much better under zero gravity conditions. Interesting experimental drafts in this field are the variation of nozzle design and shape, the effects of clearly defined disturbances on jet flow, and the interaction of two or more jets. ESA

Heat and mass transfer mechanisms of Poly Acryl Amide gels (PAA gels) photopolymerization are investigated in terrestrial experiments and with the help of numerical methods. Experiments include photoregistration of convective flows with the help of light scattering particles, investigation of the temperature and concentration fields by shadow and interferometer methods and viscoelastic measurements. Mathematical modeling is developed for describing heat and mass transfer in a polymerizing mixture under terrestrial and orbital conditions taking into account the main features of the kinetics and the rheology of the process. It is found that the buoyancy convective flows caused by the reaction exothermality and the appearance of a new more dense phase may exert marked influence on the polymerization process characteristics and on the structure of gels obtained on Earth. Under microgravity conditions the intensity of bouyancy convection is markedly less, however nongravitational types of convection might be important. The role of time averaged flows induced by high frequency vibrations is studied numerically. ESA

TWO-PHASE FLOW HEAT TRANSFER AND HYDRODYNAMICS IN AN ELECTRIC FIELD c34

M. K. Bologa, S. M. Klimov, and S. I. Chuchkalov *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 181-186 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The experimental investigation results of boiling heat transfer, mechanism and internal characteristics during R-113 boiling in narrow flat ducts and annuli under an applied electric field are presented. The influence of a direct current electric field on the two phase flow heat transfer and hydrodynamics during R-113 flow boiling and condensation in vertical narrow annuli is also investigated. Boiling heat transfer intensification in an electric field is found to be caused by a liquid microlayer thining resulting from an increase of the interface movement velocity and is accompanied by the reduction of 'dry spots'. The enhancement of low condensation heat transfer is provided by the augmentation of the vapor flow influence on the condensate film and by the additional interaction of vapor flow and the jet droplet cross flow of the liquid dispersed by the electric field. The processes occurring when a liquid drop undergoes evaporation are described. When a liquid drop undergoes evaporation, its surface temperature decreases. If the droplet is free floating in a microgravity environment, the heat transfer process inside the droplet is initially condition controlled. As the process continues, a radial temperature gradient builds up at the free surface until the critical Marangoni number is exceeded. Then the onset of instability induces thermocapillary convective flows, which in turn speed up the evaporation. The convective flows will subside when the interior of the droplet reaches a certain equilibrium temperature, and the process will return to the diffusion controlled mode. Both preliminary modeling and recent laboratory data have confirmed that Marangoni instability induced convection can and does occur in the droplet evaporation process. Mathematical models representing Marangoni instability in an evaporating liquid drop are presented. An ideal space experiment to study and characterize the onset of Marangoni instability in an evaporating liquid droplet and to establish the effect of Marangoni instability induced convection on the droplet evaporation rate is outlined and the need for conducting such experiments in space is highlighted. However, before an opportunity to conduct experiments in space arises, ground based experiments have to be conducted to study feasibility issues and proof of concept. A ground based experiment of this type is outlined. ESA

The thermocapillary motion of bubbles in a liquid environment induced by temperature gradients in the continuous phase is studied. The problem is analyzed under conditions where convective heat transfer is important, that is, for large Marangoni numbers and vanishing Reynolds number, by assuming a thermal boundary layer around the bubble. The temperature and velocity fields are determined, and the corresponding value for the terminal velocity is evaluated by an iterative procedure. The temperature field obtained is given in a form valid for arbitrary Reynolds number; this provides a more direct procedure for further numerical works. ESA

Surface tension driven flows, induced by imposed temperature differences, in plane cavities with differentially heated end walls are considered. This configuration is connected to processes of crystal growth from melt by the open boat horizontal technique. The field equations are numerically solved and the free surface shape is computed under the assumption of small capillary number. Attention is focused on the influence on the flow field structure and behavior of the aspect ratio $A = H/L$, with H and L, respectively, the height and the length of the cavity. Stream lines, isotherms, velocity profiles, and surface shapes are given and discussed; in particular, the maximum of the surface velocity, the maximum of the surface deformation and the bulk heat transfer coefficient (Nusselt number) are reported as functions of the aspect ratio and of the Peclet number. ESA

Mathematical models of convection were developed: a three Dimensional (3D) direct simulation based on Navier-Stokes equations, and a new PC based system COMGA (Convection in Microgravity) for multiparametrical study of two dimensional convection problems. The possibility of eliminating lateral macroinhomogeneities in an ampoule in semiconductor melts by slow rotation in microgravity is shown using the dialog system COMGA. A slow rotation of microacceleration vector should be used also for the elimination of longitudinal inhomogeneities in the sample. The study of convection in microgravity shows numerous opportunities of eliminating macroinhomogeneities in microgravity due to a slow rotation which should be used also in terrestrial environments as alternative control opportunities. A multiparametrical study with specialized analysis models is needed to obtain conclusions in each case of space processing. ESA

BENARD AND MARANGONI CONVECTION IN MULTIPLE LIQUID LAYERS **c34**

Jean N. Koster, A. Prakash, D. Fujita, and T. Doi (National Space Development Agency, Tokyo, Japan.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 221-226 (For primary document see N94-10070 01-29)

(Grant NAG3-1094)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Convective fluid dynamics of immiscible double and triple liquid layers are considered. First results on multilayer convective flow, in preparation for spaceflight experiment aboard IML-2 (International Microgravity Laboratory), are discussed. Convective flow in liquid layers with one or two horizontal interfaces with heat flow applied parallel to them is one of the systems investigated. The second system comprises two horizontally layered immiscible liquids heated from below and cooled from above, that is, heat flow orthogonal to the interface. In this system convection results due to the classical Benard instability. ESA

COUPLED THERMOGRAVITATIONAL AND THERMOCAPILLARY CONVECTION IN A TWO-LAYER FLUID SYSTEM **c34**

Q. S. Liu, G. Chen, and Bernard Roux *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 227-231 Sponsored by CNES (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Steady thermogravitational and thermocapillary driven flow of two immiscible liquid layers is considered in the case of a cavity subjected to a horizontal temperature gradient. The Navier-Stokes equations with Boussinesq approximation are solved numerically by a finite different method in a staggered grid. Convective patterns were emphasized numerically. They depend on property ratios of the two liquid layers and on depth fractions of the layers. Reduction of convection in the lower (encapsulated) layer can be achieved by a proper choice of the parameters. Both situations with rigid or with free top surface were considered. This latter configuration is similar to that of an encalpsulated crystal growth. The computations were performed for flat interfaces, liquid-liquid and liquid-gas. Most of them were limited to a cavity of aspect ratio A = 2 (length/height). ESA

MEASUREMENT OF THE THERMAL CONDUCTIVITY OF MOLTEN InSb IN A DROP SHAFT

Shin Nakamura and Taketoshi Hibiya *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 233-236 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The thermal conductivity of molten InSb was measured under microgravity in a drop shaft by the transient hot wire method using the Thermal Conductivity Measurement Facility (TCMF). Convective heat transfer was confirmed to be sufficiently suppressed during free fall, whereas measurements before dropping were affected by convection due to wire heating. The thermal conductivity of molten InSb was 16.7 W/m.K at 850K and 17.5 W/m.K at 870K. Thermal conductivity values obtained in a drop shaft showed the same temperature dependence as those obtained on board the TEXUS rocket. These thermal conductivities were consistent with estimations using the Wiedemann-Franz law, indicating that molten InSb is metallic. ESA

THE EFFECT OF GRAVITY MODULATION ON THERMOSOLUTAL CONVECTION

Bonita V. Saunders, Bruce T. Murray, G. B. McFadden, S. R. Coriell, and A. A. Wheeler *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 237-241 Sponsored by NASA and DARPA (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

In a gravitational field, the opposing effects of components of different diffusivities, for example, temperature and solute, in the density profile in a fluid may produce convective instabilities that exhibit a broad range of dynamical behavior. The effect of time periodic vertical gravity modulation on the onset of these instabilities in an infinite horizontal layer with stress free boundaries is examined. This work is viewed as a first step in expanding previous results in solidification to the full problem of characterizing the effects of gravity modulation in thermosolutal convection during the directional solidification of binary alloys. Calculations carried out both with and without steady background acceleration are presented, the latter results being relevant to microgravity conditions. ESA

N94-10104# Goettingen Univ. (Germany). Inst. fuer Angewandte Mechanik und Stroemungsphysik.

THERMOCAPILLARY SLUG FLOW IN A CAPILLARY TUBE **c34**

Martin Schaefer, Heinz Lang (Max-Planck-Inst. fuer Stroemungsforschung, Goettingen, Germany.), and Helmut Eckelmann *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 243-246 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The thermocapillary motion of a liquid slug in a horizontally mounted capillary tube filled with a matrix liquid was investigated theoretically and experimentally. It was found that the slug velocity U depends on the square of the film thickness h between the capillary wall and the slug, linearly on the temperature gradient dT/dx and is inversely proportional to the dynamic viscosity mu(sub 1) of the matrix liquid. A further result of the present investigations is that a critical Bond number can be defined, which is constant and a measure for the starting of the motion of the slug. Furthermore, a theory by Goldsmith and Mason, describing the influence of buoyancy on slug flow, was modified for the case of thermocapillary motion. A good agreement between experiment and theory was found. ESA

SEPARATION OF GRAVITATIONAL EFFECTS ON THE FLOW OF SUSPENSION IN TUBES BY MEASUREMENTS IN WEIGHTLESSNESS

Bernhard Schwark-Werwach and Hans J. Rath *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 247-251 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Under microgravity the influence of gravity disappears and therefore sedimentation effects are eliminated. In this case it is possible to separate effects of gravity from the interaction between solid particles, fluid and wall. A suspension of glass spheres in water was chosen as a model suspension. The pressure drop for different flow rates, tube diameters, particle diameters and concentrations of particles was measured in the turbulent region. Measurements were made under microgravity in the drop tower Bremen and during parabolic flights of aeroplanes. They were completed by measurements under Earth gravity. The method to measure the pressure drop without sedimentation of a suspension, which is heterogeneous under terrestrial gravity conditions, was successfully tested. The additional pressure drop by the particles differs from other homogeneous suspensions and depends on the tube diameter, Reynolds number and concentration. A reduction of turbulent energy dissipation was demonstrated. ESA

Transient Marangoni convection under micro and Earth gravity conditions around a gas bubble floating in a liquid filled rectangular box with adiabatic side walls, while the bottom and top walls are maintained at different temperatures, is simulated with a two dimensional model. Employing two numerical methods, a finite difference scheme with explicit time steps and a fully implicit control volume finite element method, the enhancement of the heat transfer in the liquid matrix due to Marangoni convection is investigated in parallel. To simplify the calculations, the bubble is fixed at a certain location in the container, while the necessary transient force to hold the bubble in place is determined. For a test fluid with Prandtl number equal to 1.93, the transient overall heat transfer and fluid flow are examined for several configurations of bubble and container in terms of the dimensionless numbers Nusselt number and Marangoni number. Contrary to the very common view that the gas bubble would reduce the heat transfer due to its insulating behavior, the energy transport is rather augmented by the Marangoni convection acting on the free surface of the bubble. The numerical simulations show that Marangoni convection can fully replace buoyancy induced heat transfer mechanisms in a microgravity environment. In contrast to former assumptions, Marangoni flow is, in general, not negligible. The transient development of fluid flow and heat transfer was calculated; only the final steady state results are presented. ESA

BOUNDARY LAYERS ALONG HORIZONTAL FREE SURFACES DUE TO COMBINED EFFECTS OF TEMPERATURE AND CONCENTRATION GRADIENTS **c34**
Antonio Viviani and R. Savino *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 265-272 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Boundary layers along horizontal free surfaces due to buoyancy forces and surface tension gradients, arising from combined effects of temperature and concentration gradients are considered. A similarity analysis is performed in combination with a nondimensional order of magnitude analysis that give, at the same time, the a priori conditions for the existence and characterization of all possible flow regimes, and the conditions for the existence of similar solutions. The numerical results are presented for Prandtl and Schmidt numbers ranging from liquid metals to silicon oils and different values of the similarity parameters. In the more general case of double diffusive boundary layers, the computed profiles are discussed for typical Prandtl and Schmidt numbers of interest in melt crystal growth, in both the cases of aiding or opposing thermal and solutal driving actions. A flow visualization technique, which combines Particle Image Velocimetry (PIV) and the liquid crystal tracer technique, for the simultaneous measurement of temperature and velocity fields of thermoconvective liquid flows, is introduced. This technique was applied to the so called Benard convection between two horizontal plates. Additionally, laser doppler velocimetry measurements were performed for the verification of experimental and theoretical predictions. Experimental techniques and results are discussed. ESA

Software models and experimental benches for studying some of the physical aspects of the fluid motion in a zero gavity environment are described. These tools are used in the design, development and testing of Propellant Management Devices (PMD's) which provide gas free propellant from the tanks to the thrusters during the life of a spacecraft. PMD's and their validation in simulated low gravity using bubble point measurements and neutral buoyancy tests are addressed. ESA

An overview of instrumentation and technologies developed under the European Space Agency's Technology Research Program is given. The initiation phase of a gas film positioning system for processing glasses at advanced temperatures above 700C was completed. Acoustic levitation and containerless processsing were performed with proteins and glasses. Diagnostic techniques, appropriate cuvette and window designs enabling interactions according to the investigated process status and experiment requirements during fluid dynamic and solution growth experiments are intended and latest results are included. Light scattering techniques, similar to those applied to monitor protein crystal growth, are identified as a potential useful microgravity research tool for glasses and aerosols. Developments of appropriate diagnostic instruments dedicated to such applications under microgravity are planned and an overview of technology approaches is given. ESA

Lundstroem (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 297-300 Sponsored by ESA and Dornier (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A simple instrument technique for temperature measurements around a burning droplet in microgravity conditions was developed. To this purpose the 'anomalous' Laser Induced Fluorescence (LIF) of pyrene was tested in the case of liquid hydrocarbon fuels. The pyrene spectrum exhibits two bands (350 and 395 nm) whose ratio is sensitive to the temperature. A rugged Nd:YAG laser case was used for the excitation of pyrene vapor at 266 nm in seeded flames. Spectral investigations were performed with an optical multichannel detector. Temperatures of flames generated by a porous sphere burner fed with liquid fuel were measured and compared with the corresponding thermocouple measurements. The results indicate that the pyrene LIF technique is suitable for temperature measurements of n-octane flames in the 700 to 1200K range with less than +/- 100K data spread on single measurement points from shot to shot. Future developments might involve the use of a charge coupled device camera to perform single shot two dimensional imaging of the temperature fields in different kinds of flames. ESA

A NEW METHOD FOR HYSTERESIS MEASUREMENTS DEVELOPED FOR C(SUB v) MEASUREMENTS AT THE CRITICAL POINT DURING THE D2-MISSION **c35**
Johannes Straub, Axel Haupt, K. Nitsche, and Kurt Kemmerle (Kayser Threde G.m.b.H., Munich, Germany.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 301-308 Sponsored by BMFT (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The method and design of the High Precision Thermostat (HPT) calorimeter, used for the study of the hysteresis of the specific heat capacity C(sub v) between heating and cooling ramps, are described. The HPT used during the D1 mission is now modified for the D2 mission. The new design provides the possibility to measure C(sub v) in the critical region both during heating and cooling runs at an enlarged temperature range. The unexpected results of the first microgravity measurements of C(sub v) performed during the D1 mission can be explained by an asymmetrical mass distribution in the cell. There the sample was heated electrically, which provides highest accuracy in measuring caloric data, that is, C(sub v), but only measurements from the two phase region into the one phase region are possible. Even at smallest temperature ramps (D1:+3.6 mK/h) the thermodynamic equilibrium can not be reached, which is seen as the reason for the unexpected results of the D1 mission. The new calorimeter is constructed in such a way, that the measurements start in the homogeneous density region above critical temperature, and the sample is cooled down into the two phase region. In microgravity the density will remain homogeneous down to critical temperature and it is anticipated that the real value of C(sub v) can be observed not being influenced by density stratification. A fluid sample of SF6 at the critical density is enclosed in a spherical cell; the energy transport between it and the surrounding shell, which can be heated and cooled continuously, takes place by radiation. By measuring the temperature difference between them as well as the temperature ramp of the sample cell itself, the heat capacity C(sub v) is determined. ESA

CONCEPT AND DESIGN OF AMPOULE FOR MELT GROWTH OF GALLIUM ARSENIDE IN FIRST MISSION OF SPACE FLYER UNIT
Satoshi Adachi, K. Takahashi, M. Watanabe, Y. Ikegami, J. Ochiai, M. Kuribayashi, and H. Sakai (Institute for Unmanned Space Experiments Free Flyer, Tokyo, Japan.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 311-314 Sponsored by New Energy Development Organization, Tokyo, Japan (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The experimental set up to be installed in the first mission of the space flyer unit for melt growth experiments of gallium arsenide is described. The aim of the experiments is to obtain crystals with uniform concentration of dopant. In order to obtain such crystals, sufficient suppression of the Marangoni convection is required. The design of the gradient heat furnace and ampoules is described. The present design of the ampoule for the crystal growth consists of three parts, that is, the crucible, the vacuum seal, and the sample case. Although an arsenic vapor source is not employed in this ampoule, the stoichiometric change in the melt is negligibly small due to the elimination of the excessive space in the ampoule. The crucible would well reduce the Marangoni convection by covering the melt with the rigid wall. In the case of the melting zone length of 35 mm, the length of the uniform concentration is obtained as about 20 mm from the results of numerical calculation of the diffusion equation. ESA

To ensure axisymmetric growth conditions and to accelerate mass transfer from the dissolving to the growing interface the experiment on CdTe crystal growth employing the Travelling Heater Method (THM) and a rotating magnetic field was carried out during the Photon 7 mission in the Zona 4 facility in Oct. 1991. The ampoule had an inner diameter of 15 mm. To prepare the flight experiment, a mathematical modeling of the physico-chemical processes in the solution zone, the processes of a dissolving and growth was performed. It is shown that the magnetic field has great influence on the growth conditions. Studies of the grown crystal are being caried out. ESA

An overview of the Liquid Structure Facility (LSF) architecture, a multiuser multimission experimental facility capable of performing fluid sciences experiments related to surface tension, thermal behavior diffusion, concentration and surface deformation phenomena is given. The LSF was preliminary designed for a Spacelab mission, however, the design analysis takes into account the accommodation on future Columbus missions. The diagnostics fit in the facility is described from a theoretical and experimental point of view. Since the idea of a real multiuser facility dedicated to the fluid physics community has been initiated, the LSF has gone through an evolutive process which now can produce for the scientists a tool dedicated to its specific needs. This is achieved thanks to the modularity of its set of diagnosis tools and to the choice of a standard link to control and to monitor the intelligent cell module. The last development and technical choices related to the LSF made possible the experimental evaluation of the diagnosis performances in terms of feasibility, application range, accuracy, and sensitivity. The facility concept, reactor design, and latest developments of the Advanced Protein Crystallization Facility (APCF), a multiuser facility for protein crytallization experiments under microgravity, are described. First space flights are planned for 1993 (Spacelab) and 1994 (IML-2 (International Microgravity Laboratory)). In the APCF, 48 experiments can be accommodated under controlled temperature conditions and partly under video observation of the crytallization process. Three types of protein reactors were developed. These allow protein crystallization according to the methods liquid-liquid diffusion, dialysis, and vapor diffusion (hanging drop). New developments include another type of hanging drop reactor with active controlled diffusion and the upgrade of the APCF for the diagnostic methods. ESA

Traditional separation techniques are inadequate for many new bioprocessing challenges. Innovative separation methods such as aqueous two phase partitioning are needed to perpetuate bioprocess commercialization. Aqueous two phase polymer partitioning systems provide a process for separating biological materials when combined with microgravity. An innovative space qualified apparatus developed for carrying out separations by partitioning in immiscible polymer systems under mirogravity conditions is described. The apparatus offers an innovative approach to low gravity bioseparations in general and phase partitioning in particular. These capabilities support NASA's interest in serving the biotechnology research community and providing quantitative data in the gravity dependent components of separation processes. ESA

CALIBRATION OF ACCELEROMETERS ON DROP TOWER BREMEN **c35**

U. Kaczmarczik, Hansjorg Dittus, and Hans J. Rath *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 343-347 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Accuracy of accelerometer calibration under normal Earth gravity has a limit of about 0.001 m/sq s approximately equal to 0.0001 g(sub 0) in resolution (g(sub 0) acceleration of normal Earth gravity). The most important error influence is the accelerometer cross sensitivity that produces an additional bias error. Under microgravity conditions disturbing cross sensitivities can be neglected. The new ZARM (Center of Applied Space Technology and Microgravity, University of Bremen, Germany) accelerometer calibration device uses the excellent microgravity conditions of drop tower 'Bremen' to achieve better calibration accuracy. The device is specially designed to calibrate the well known quartz flexure sensors for navigation purposes. Other sensor types can be easily adapted by changing the mounting frame and the amplifier. The quality of this device will be shown by testing a high performance quartz flexure sensor (type JA 5L14). ESA

Bugeat (Societe Europeenne de Propulsion, Moissy-Cramayel, France.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 349-356 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The overall design and main features of a gas film levitator foreseen for containerless processing of glasses in microgravity conditions are presented. The scientific motivations in favor of the development of this multiuser facility and the scientific requirements in stimuli/performances are reviewed. A high temperature mock up of the foreseen facility was designed, manufactured, and tested in order to establish: the feasibility of the overall design concept and of the most critical technologies; and the feasibility of containerless processing of bulk glass samples in the tubular gas film levitator. Large cylindrical glass samples (diameter 15 mm, length 10 mm) were containerlessly processed up to 1250C on ground in this facility. Even larger samples (up to 60 mm length) will be processed in microgravity conditions up to 1500 to 1600C. ESA

During the D1 mission the HPT (High Precision Thermostat) produced surprising results regarding the behavior of C(sub v) of SF6 at its critical point. One-g reference tests with the flight unit proved the microgravity origin of the observed phenomenon. It was hypothesized that these results may be due to nonequilibrium and hysteresis effects. Thus the demand for a modified experiment measuring the hysteresis of the specific heat of SF6 at its critical point arose. Additionally, the measuring range around the critical point should be enlarged considerably. This experiment is known as HYDRA (Hysteresis of the specific heat During heating And cooling through the critical point) and will fly on the D2 mission. The necessity of this modified experiment had impacts on the functional concept and on the set up of the HPT. The modifications which had to be installed and the new performance data are described in detail. ESA

TEMPUS: AN ELECTROMAGNETIC LEVITATION FACILITY FOR CONTAINERLESS PROCESSING UNDER MICRO-g IN SPACELAB
Richard Knauf, J. Piller, A. Seidel, and W. Dreier (Deutsche Agentur fuer Raumfahrtangelegenheiten G.m.b.H., Bonn, Germany.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 367-372 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noorwijk, Netherlands, HC

TEMPUS, an electromagnetic levitator with inductive heating and positioning that allows containerless processing of metallic samples up to 2400C under ultraclean environmental conditions, is presented. Containerless processing under microgravity is one key technology in microgravity materials science research which allows study of the formation of metastable phases, nucleation phenomena, as well as important thermophysical properties like heat capacity, surface tension, and viscosity of high melting materials. A Spacelab version of TEMPUS that is based on an already built laboratory model (which was also tested on parabolic KC 135 flights) and a sounding rocket payload flown within the TEXUS program is being developed. This Spacelab model is a payload element of the U.S. microgravity Spacelab mission IML-2 (International Microgravity Laboratory) to be launched in Jun. 1994. Main features are the nearly independent control of the RF heating and positioning power down to lowest values and the extensive diagnostic devices in the visual and infrared regime, combined with elaborate sample stimulation capability. Comfortable commanding and reprogramming capabilities allow telescience experiments as well as quasi-automatic processing. ESA

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The development and the test results of an electron beam furnace for the utilization in a microgravitational environment are reported. The furnace hardware which can be divided into three major parts is described: electron beam gun, electron optics and diagnostics, and a process chamber including sample and optical sensor system. The optical sensor and control system are described. By just varying the deflection pattern by means of the electron optical components two different types of thermal profiles, a gradient profile with a slope of 200 K/cm, and a hot zone profile with a maximum zone temperature of 1520 K could be established and maintained. A beam power of 550 W had to be applied to a sample out of massive Ta for the gradient profile; for creating a hot zone profile, an input power of only 250 W onto a sample with a ceramic core was sufficient. A continuous pyrometric measurement system with a high local and time resolution has been realized. Temperature sensing with this system reflected an intrinsic feature of electron beam heating: the sharply localized energy deposition at the sample surface. ESA

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

There is a growing body of theoretical and experimental evidence suggesting that the uniformity, rate, adhesion, quality, and other key properties of Chemical Vapor Deposition (CVD) diamond coatings are influenced by the gas mixing kinetics in the thermal plasma environment of the reaction chamber. The implementation of, for example, Microwave Plasma Enhanced Chemical Vapor Deposition (MPECVD) process in microgravity has, thus, been suggested. Such a diamond deposition system, which overcomes the limitations of present systems and which is distiguishable from them by the use of high pressure MPECVD and recirculation of the would be effluent hydrogen and carbon, is described. Given the key fact that there is nothing in the effluent of the MPECVD process that is truly a byproduct or 'waste', the system can, at least in principle, lend itself to being closed loop yet dynamic. The exhaust contains hydrogen and carbon species which can be recirculated to the plasma reactor, that is, since there are no unusable reaction byproducts, the effluent can be fed back to the reaction chamber with no detriment, thus allowing deployment in a microgravity environment. ESA

MICROGRAVITY APPLICATIONS FURNACE FACILITY (MAFF) FOR PARABOLIC FLIGHTS
Christian Lockowandt, K. Loeth, Lars Ekbom (Royal Inst. of Tech., Stockholm, Sweden.), A. Eliasson (Royal Inst. of Tech., Stockholm, Sweden.), and Anders E. W. Jarfors (Royal Inst. of Tech., Stockholm, Sweden.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 383-386 Sponsored by Swedish Board for Space Activities, and ESA (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The Microgravity Applications Furnace Facility (MAFF), which is used for high temperature microgravity processing metals, alloys, and composites in parabolic flights, is addressed and its applications are given. The facility is able to melt, maintain the temperature, and solidify a sample during the microgravity periods of 20 seconds given during a parabolic flight. MAFF is equipped with six IR heated furnaces. The radiation from halogen lamps is focused on the sample with ellipsoid mirrors. A cooling system enables active cooling of the samples. Data is collected and the furnaces are controlled by a computer (PC). An experiment to study the dissolution of solid aluminum carbide particles and precipitation of solid titanium carbide particles in liquid aluminum is reported. The study of precipitation morphologies, under normal gravity conditions, is impossible due to large convective motions. The effect of both temperature and composition were investigated. A further experiment which investigated liquid phase sintering of tunsgten composites in microgravity is reported. ESA

FORCE AND POWER EFFICIENCY OF MICRO-g ELECTROMAGNETIC LEVITATION COILS

Georg Lohoefer *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 387-390 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The study of undercooled liquids requires containerless sample handling to avoid nucleation at container walls. For electrically conductuing bulk samples this can be obtained by using the electromagnetic levitation technique, where the material is contactlessly positioned and heated in one or several alternating magnetic fields. An efficiency optimized microgravity coil system, which is also used in the microgravity levitation facility TEMPUS is presented. Data on its heating efficiency and force-power relation depending on the sample conductivity is also given. ESA

HIGH TEMPERATURE PROCESSING AND DIAGNOSTIC TECHNOLOGIES FOR MICROGRAVITY APPLICATIONS

A. Lundstroem and Matthias Dieckmann *In its* Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 391-394 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

An overview of high temperature processing techniques and diagnostic instrumentation for materials science developed under the European Space Agency's Technological Research Program is given. On the space processing side, electron beam and induction heating are investigated together with resistance furnaces with 2000 C capability. The integration of magnets in furnaces to achieve magnetic damping of residual flows is being studied at breadboard level for crystal growth applications. Studies on new cartridge technologies compatible with these developments were also initiated. On the diagnostic side, pyrometry was improved by avoiding window contamination. Thin film thermocouples are under development allowing miniaturized arrays for high density of instrumentation with minimal disturbances for the experiments. Ultrasound techniques are explored for flow field mapping and solid-liquid interface detection in opaque melts. ESA

DETERMINATION OF THE VISCOUS ACOUSTIC FIELD FOR LIQUID DROP POSITIONING/FORCING IN AN ACOUSTIC LEVITATION CHAMBER IN MICROGRAVITY

Margaret J. Lyell *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 395-397 (For primary document see N94-10070 01-29)
(Contract NAG3-1005)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The development of acoustic levitation systems has provided a technology with which to undertake droplet studies as well as do containerless processing experiments in a microgravity environment. Acoustic levitation chambers utilize radiation pressure forces to position/manipulate the drop. Oscillations can be induced via frequency modulation of the acoustic wave, with the modulated acoustic radiation vector acting as the driving force. To account for tangential as well as radial forcing, it is necessary that the viscous effects be included in the acoustic field. The method of composite expansions is employed in the determination of the acoustic field with viscous effects. ESA

MUZO: THE PROGRAMMABLE MULTI ZONE FURNACE FOR GAS PAYLOADS AND SOUNDING ROCKETS

Henrik Malmstroem and Torbjorn Carlberg (Sundsvall Univ., Sweden.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 399-402 Sponsored by Swedish Board for Space Activities (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The Multi Zone (MUZO) furnace, developed for high temperature experiments in a Get Away Special (GAS) payload, is presented. MUZO is also suitable for use in sounding rockets such as MASER and MAXUS (7 to 14 minutes microgravity). The furnace is built around a ceramic tube with five independent heating elements and a gas cooling system. A sophisticated computer control system was developed consisting of five separate regulators using information from 15 thermocouples. In order to characterize the furnace performance, in terms of convection level in the melt, axial concentration profiles in germanium crystal doped with gallium were studied under 1 g conditions. ESA

THE SURFACE PLASMON SPECTROSCOPY AS DIAGNOSTIC TECHNIQUE IN MICROGRAVITY EXPERIMENTS

G. Margheri, Matteo Tacconi, and P. G. Falciani *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 403-405 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The performance of an experimental apparatus using the Surface Plasmon Spectroscopy (SPS) with a Kretschmann like coupling configuration is analyzed. The growing film deposited in a metal film (whose dielectric constant and thickness have to be accurately measured before the deposition process) is directly evaporated on the face of a glass prism. The method is very helpful to resolve interfacial deposition layers of the order to some A. Simultaneously, the SPS equations allow the very precise determination of the characteristics of the metal layer in which the deposition occurs (thickness, dielectric constant). It is shown that with a coupling configuration using conical beams and an area array (Charge Coupled Device (CCD)) as sensor, it is possible to design very compact and simple experimental modules with minimum optomechanical moving parts. ESA

TOLS (TELESCIENCE ON-LINE SIMULATOR): AN ESSENTIAL INSTRUMENT FOR MICRO-GRAVITY INTERACTIVE EXPERIMENT c14

Raimondo Fortezza and Rodolfo Monti (Naples Univ., Italy.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 407-411 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The telescience operative mode represents for the investigator the capability to perform a scientific interactive experiment directly from the ground. Interaction means that the scientist is able to take appropriate actions and to modify the experiment execution on the basis of the data, video, and, more in general, information that he receives directly from the onboard facility. The scientific knowledge and expertise of the investigator ensures a more intelligent control, guarantees best results, and limits the involvement of the crew onboard (if any). The capability to perform the experiment directly from a ground based facility, with an approach similar to that used to carry out the research in an on ground laboratory, represents the final objective. To reach this goal it is required to establish communication links that are completely transparent to the scientist and to design specific devices able to provide support in the experiment control and management. Some such devices developed to support several experiments performed, using telescience approach, on sounding rockets are illustrated. These consist of hardware and software tools that simulate the experimental processes in real or quasi-real-time, visualize in a quick look format the relevant data, and help the investigators to take the appropriate decisions during the course of the experiments. The future development of these tools is also considered. ESA

LASER BEAM DEFLECTION: A DIAGNOSTIC TOOL FOR VAPOUR GROWTH EXPERIMENTS IN MICROGRAVITY
Sergio Musazzi, A. Torinesi, F. Trespidi, and Michael Braun (Dornier System G.m.b.H., Friedrichshafen, Germany.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 413-417 (For primary document see N94-10070 01-29)
(Contract ESTEC-7337/87/NL/PB(SC))
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

While the growth of bulk crystals and thin layers from vapor is a method with increasing importance and great potential, the theoretical understanding of this technique is quite limited. In particular, the influence of impurities and natural convection on the transport mechanism is not well understood. Density gradients in the vapor phase can be measured by the deflection of a laser beam traversing the growth cell perpendicular to the main direction of material transport. The suitability of this method was demonstrated in a laboratory set up using iodine as reference material. Optical gradients dn/dz less than 0.000001/cm can be detected over a 1 cm depth region of transport. The results of the first experiments are in the range predicted by theory. Since the beam deflection apparatus can be tailored to fit a quite small volume and does not require exhaustive diagnostics instrumentation or data processing, it can easily be adapted to a spaceflight experiment. The general design of the Advanced Fluid Physics Module (AFMP), a multipurpose multiuser facility dedicated to research on basic phenomena of fluid behavior in a microgravity environment, is introduced. Its accommodation for the Spacelab D2 mission is described. In the course of the AFMP technical development, the performance of the instrument was upgraded to ensure that scientific objectives set for the five experiments on board Spacelab D2 could be met. In addition, specific experimental equipment, in the form of discs and a cell, were developed to be mounted on the AFMP for the experiment realization to provide superior experimental capabilities to the AFPM facility. Activities carried out to assess the performance of a nonintrusive diagnostic technique (Particle Image Velocimetry (PIV)), which is used to study combustion problems relevant to microgravity research, are described. A setup for production of suitable flames and an instrument to implement PIV was previously developed. To assess the performance of this instrument, a calibration device was used. The calibration device consists of a disk with a flat front surface, on which tracers are deposited. This surface is illuminated by a time modulated light sheet. The disk is made to rotate at a controlled speed. An error analysis is presented concerning the calibration device and the Young fringe analysis involved. This error analysis is supported by a set of trials, which also give an estimation of both the systematic and random errors involved as well as the dynamic range of the instrument. ESA

RESULTS OF MISSION PREPARATION SUPPORT TO MICROGRAVITY EXPERIMENTS ON BOARD OF EURECA 1
H. P. Schmidt, M. Exner, W. Koerver, C. Krug, C. Lindberg, B. Paetz, T. Neuhausen, and K. Strauch *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 429-432 (For primary document see N94-10070 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Concept and facilities of the experiment preparation and the mission support program for Eureca 1, given by the Microgravity Support Center (MUSC) in Cologne (Germany), are discussed. Eureca will be used to conduct experiments in microgravity. The support covers essential parts of the experiment preparation and the experiment execution during the mission. The engineering models of the experiment facilities were used to run simulation experiments for development and verification of experiment control parameters and procedures. During the mission, the user support center will take care of the processing of telemetry data generated by the experiment facilities in space. It will also support the investigators in the control of the experiment performance. ESA

ANALYSIS OF THE ALIGNMENT OF A SCHLIEREN SYSTEM FOR TELE-OPERATION
F. H. P. Spaan and A. J. Kramer *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 435-440 (For primary document see N94-10070 01-29)
(Contract NIVR-02905N)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A theory for alignment of the gratings of the multiple source schlieren system, which can be used in microgravity experiments, was developed and verified by experiments. The results indicate the feasibility of reliable teleoperated or automated alignment for fast and accurate alignment. Due to hardware limitations, some minor problems were identified in the region very close to optimal alignment. Analysis of the so called bright spot intensity profile of Prototype Optical Diagnostic Instrument (PODI) revealed a slight suboptimal position of the lens (unsharp imaging). It was shown that a teleoperated/automated alignment procedure for the sharp focusing schlieren system can be operated successfully. It encourages further development of tools for teleoperation or automation assistance for optimization of parameters of (spaceborne) diagnostical instruments. It is suggested that future work may include studies on tools for schlieren lens adjustment and focusing. ESA

AGF (AUTOMATIC GRADIENT FURNACE): A PROPOSED MICROGRAVITY FACILITY

Hans M. Tensi and Raimund Roesch *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluids Sciences in Microgravity, Volume 1 Aug. 1992 p 441-446 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The Automatic Gradient Furnace (AGF) with quenching device, proposed in Mar. 1991 as a facility development for the Columbus precursor flights especially for Eureca missions, is presented. The experimental selection of these microgravity missions is still pending. The proposed AGF is planned for unidirectional solidification of metallic and nonmetallic samples with quenching of the solidification front and the residual melt in a microgravity environment. The furnace is automatically regulated to the parameter requirements of the experimenter, automatically comparing the actual (measured and calculated) crystallization parameters (solidification rate and thermal gradient in liquid ahead of the solidification front) with the nominal values. After quenching, the specimen is automatically changed. ESA

MICROGRAVITY EXPERIMENTS USING TR-1A ROCKET

Schinichi Yoda, T. Nakamura, S. Yoshitomi, and M. Saito *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 447-453 (For primary document see N94-10070 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The objectives, hardware development, and microgravity experiments performed during the first flight of the TR-1A are addressed. Six experiment systems were developed for the first flight experiment: the crystal growth experiment equipment; the fluid dynamics technology experiment equipment; the bubble generation; dynamics and handling experiment equipment; the isothermal furnace; and the high temperature heating furnace. The TR-1A was launched on 16 Sep. 1991 to study Marangoni convection flow, bubble gerneration mechanisms, crystal growth from solution, melting and solidifying of particle dispersion strengthened alloy with different wettability between the particle and matrix, and high temperature oxide superconductors using the above equipment. All experiment sequences were performed satisfactorily for each system. Video cameras properly recorded the behavior such as melting of materials, liquid flow, bubble formation and combinations, and crystal growth behavior. ESA

EXPERIMENTAL APPROACH TO NON-CONTACT CALORIMETRY IN SPACE

Rainer K. Wunderlich, Angelika Diefenbach (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne, Germany.), Rainer Willnecker (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne, Germany.), and Hans-Jorg Fecht *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 1 Aug. 1992 p 455-460 (For primary document see N94-10070 01-29)
(Contracts DARA-50-WM-9110-5; DARA-50-QV-9101)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Ground based experiments were performed to verify the applicability of noncontact calorimetry in space for the determination of the thermodynamic properties of undercooled liquid metals and alloys with relatively high melting temperatures. In this method, a sample is exposed to an amplitude modulated radio frequency heating field and the dynamic temperature response of the sample is detected by noncontact temperature measurements. The experimental set up used for the ground based experiments is described. The first results on solid niobium samples demonstrating the validity of this new method are given. ESA

ON THE ROLE OF SORET EFFECT IN CONCENTRATION DISTRIBUTION IN CRYSTALS GROWING FROM THE MELT c76

Stefan VanVaerenbergh, J. C. Legros, and Marcel Hennenberg *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 469-474 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The nonconvective transport processes which may govern the concentration profile in the liquid phase near a crystallization front are considered. Such transport processes may govern, for example, in absence of buoyancy and surface tension forces or when the diffusion boundary layer is large enough. The concentration profiles are then governed not only by rejection and diffusion processes, but also by thermodiffusion. In such situations, there are significant couplings between thermal and solutal variations, near and at the interface, that influence the concentration distribution near the solidification front and consequently, in the solidified phase. This problem is analyzed for a crystal growing from the melt. The conditions of existence of oscillatory regime are deduced from a model with a semi-infinite liquid phase. ESA

SOLIDIFICATION IN IMMISCIBLE SYSTEMS: THE INFLUENCE OF PROCESSING CONDITIONS ON RESULTING MICROSTRUCTURES

J. Barry Andrews, R. A. Merrick, and A. L. Schmale (National Academy of Sciences - National Research Council, Washington, DC.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 475-480 Sponsored by NASA. Marshall Space Flight Center and NSF (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Research carried out over the past two decades in which attempts have been made to produce desirable microstructures in immiscible alloys is reviewed. Factors affecting the formation of desirable microstructures in immiscible alloys are addressed and some of the techniques that have been successful in controlling these factors in order to produce useful structures are discussed. Some of the intended applications of these alloys require a dispersion of one phase in the other, while other applications favor the use of aligned, fibrous microstructures with continuity of both phases. The microstructures obtained in immiscible alloys are often strongly influenced by processing conditions. Perhaps the most well known effect is gravity induced sedimentation of the denser immiscible phase during solidification. This difficulty with sedimentation led to low gravity processing in attempts to produce dispersed microstructures. However, experimentation under low gravity conditions soon revealed that many other factors, including wetting of the crucible walls and surface tension driven flows, often resulted in complete separation and coalescence of the two immiscible phases. The production of aligned fibrous microstructures in hypermonotectic alloys appears to be even more difficult than the formation of a dispersion. Here, in addition to sedimentation and crucible wetting, convective and interfacial instabilities must be considered as well. Calculation of the limits of stability during directional solidification were carried out but require experimental verification. ESA

Mennella (Osservatorio Astronomico, Capodimonte, Naples, Italy.) et al *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 481-488 Sponsored by Italian Space Agency (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The aim, activity, and some preliminary results of the STARDUST program are presented. The condensation of solid materials from the vapor phase is important in several scientific fields such as chemical vapor deposition, air pollution, and the formation of refractory cosmic dust around stars. Conventional studies of refractory grain formation, using high temperature furnace and shock tube techniques, are restricted to short time scales and suffer from buoyancy induced convection that limit their accuracy. In order to simulate more accurately the condensation of refractory grains near stars and to investigate the advantages of performing condensation studies in microgravity conditions, an experimental investigation of vapor phase condensation in microgravity was undertaken. The experimental equipment currently used is reported. The results from the first flight series and particle aggregation modeling efforts are presented. ESA

(For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

To clarify the contribution of thermal convection on the growth rate in supercooled melts, an experimental study of the unidirectional solidification of a liquid crystal was executed under normal and microgravity conditions. The Laser Interferometric Observation System (LIOS) launched by MASER 4 in Mar. 1990 was employed. The liquid crystal, 4-cyano-4'-5-alkoxy biphenyl (Merck), was used as a model material. Two kinds of phase change, isotropic-nematic and nematic-solid phase changes, were observed in the same run under the conditions of normal and microgravity. Microconvection in the supercooled melt was observed at the nematic-solid interface on the ground and disappeared under microgravity. Unknown oscillation of the growth rate was confirmed as a result of enhanced supercooling in the absence of microconvection. It is confirmed that the microconvection induced by latent heat diminishes supercooling and suppresses the growth rate of solid phase on the ground. The observed phenomena were modeled using Landau-Ginzburg type potential. ESA

MARANGONI MOTION DURING MELTING OF A HYPERMONOTECTIC ALLOY: NUMERICAL SIMULATIONS FOR THE D2 EXPERIMENT IHF04

c76

L. Ratke, S. Diefenbach, B. Prinz (Metallgesellschaft A.G., Frankfurt am Main, Germany.), H. Ahlborn (Technische Univ., Hamburg, Germany.), and Berndt Feuerbacher *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 495-501 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The scientific objectives, experimental procedure, numerical simulation, and expected results of the D2 experiment IHF-04, in which the Marangoni transport of Bi droplets in an Al-Si melt will be investigated by directional melting of sandwich like samples of Al-Si-Bi alloys, are addressed. The sandwich like samples consist of periodically arranged cylinders of an Al-Si alloy in which 5 wt percent Bi are distributed as droplets and cylinders of an Al-Si-Bi alloy of exact monotectic composition and being thus free of Bi droplets at the processing temperature. Ahead of the melting front there exists a temperature gradient which leads to a motion of the droplets within the Al-Si matrix melt. Bi droplets move from the cylinder with hypermonotectic composition into the droplets free one as soon as the melting front moves into it in a controlled way. At the end of an experiment a large number of droplets will be located within the molten zone. From the spatial arrangement of the droplets and a comparison with computer simulations of the whole process, conclusions are drawn concerning the Marangoni motion of Bi droplets. The investigations are relevant for the improvement of terrestrial industrial casting processes of bearing alloys. ESA

THE EFFECT OF GRAVITATIONAL MODULATION ON CONVECTION IN VERTICAL BRIDGMAN GROWTH

Bruce T. Murray, S. R. Coriell, G. B. McFadden, and A. A. Wheeler (Bristol Univ., England.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 503-506 Sponsored by NASA, Washington (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

During vertical directional solidification of a binary alloy at constant velocity, buoyancy driven solutal convection may occur due to the solute gradient associated with the solidification process. This problem is further complicated if time periodic forcing is considered, which is relevant to materials processing in a microgravity environment or as a means of dynamic control of flow instabilities. The effect of time periodic modulation is studied by introducing a gravitational acceleration which is a sinusoidal function of time. The onset of solutal convection is treated by a stability analysis of the linearized governing equations and boundary conditions. Solutions are obtained numerically by employing two distinct computational implementations of Floquet theory. Results for materials with large Schmidt number are presented, and an analysis for large frequency and large Schmidt number yields a more complete description of the behavior in this relevant limit. NUMERICAL CALCULATION OF THE GROWTH OF InP BY THE TRAVELLING HEATER METHOD IN THE FIRST MISSION OF THE SPACE FLYER UNIT **c76**

K. Takahashi, Satoshi Adachi, M. Watanabe, Y. Ikegami, J. Ochiai, M. Kuribayashi, and H. Sakai (Institute for Unmanned Space Experiments Free Flyer, Tokyo, Japan.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 507-511 Sponsored by New Energy and Industrial Technology Development Organization (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The possibility of constitutional supercooling occurring in InP crystals grown in space and on the ground by the Travelling Heater Method (THM) was determined by numerical computation. This was done in preparation for the growth of these crystals using the image mirror furnace on the first mission of the Space Flyer Unit in 1994. In THM the quality of the crystals depends on whether or not constitutional supercooling occurs. For this purpose, thermal convection, Marangoni convection, diffusion, solute (posphrous) transport, and isotherms in solution zone of InP were calculated using the model of cylindrical coordination. It was anticipated that a free surface would appear in the center of the solvent surface and a linear pattern would be assumed for that temperature distribution at the solvent surface. ESA

SCIENTIFIC SPECIFICATIONS FOR AN AUTOMATED FACILITY FOR GROWING LARGE SEMICONDUCTING CRYSTALS FROM THE MELT IN SPACE

Thierry Duffar, J. P. Nabot, C. Barat, Jean-Jacques Favier, and G. Cambon (Centre National d'Etudes Spatiales, Toulouse, France.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 513-517 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Scientific specifications of a new facility, called Sesame (a Bridgeman machine), are given in order to get the best possible large crystals (5 by 25 cm) of ternary semiconductors in space. Optimal growth conditions (growth rate, thermal gradients) are determinated to minimize dislocations density, interface destabilization, and convection. The gravity levels, interface curvature, and thermal and pulling stability are computed in order to get chemical heterogeneities less than 1 percent (both longitudinal and radial). It is shown that use of a magnetic field during an unmanned mission is necessary to achieve this goal. ESA

VARIATIONS OF THE TEMPERATURE PROFILE IN THE GRADIENT FURNACE GFQ WITHIN A CYLINDRICAL SAMPLE USED FOR DIRECTIONAL SOLIDIFICATION **c76**

Martin Stehle and S. Rex *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 521-526 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

In preparation for the Spacelab Mission D-2, the temperature profile within samples of the alloy Cu-Mn inserted in the gradient furnace GFQ was determined as a function of the heater temperature, the atmosphere within the furnace chamber, the relative sample position, and the pulling speed. These furnace parameters determine the steady state temperature profile in the sample as well as the shape and the relative position of the solid-liquid interface during the directional solidification. The experiments result in a set of parameters by which the solid-liquid interface is located on Earth close to the nominal position. Also, in microgravity this parameter set will guarantee a plane solidification front and a sufficiently high cooling rate to fix the interface at the actual position by quenching. ESA

NUMERICAL SIMULATION OF MULTI-DROPLET HYDRODYNAMIC INTERACTIONS IN LIQUID DISPERSIONS **c34**

S. Diefenbach, X. Zhang (Colorado Univ., Boulder.), R. H. Davis (Colorado Univ., Boulder.), and L. Ratke *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 527-532 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The velocities and trajectories of three and four droplets interacting hydrodynamically were determined theoretically using asymptotic solutions for two droplet arrangements and a pairwise addition scheme describing the disturbance velocities, in the case of buoyancy driven motion. The numerical calculations are compared with dedicated experiments. The agreement between theoretical predictions and experimental data is very good, though decreasing with increasing number of particles. The calculation procedure developed is applicable to the case of real multiparticle dispersion, found in immiscible alloys. ESA

FLOW TRANSITIONS IN A 2D DIRECTIONAL SOLIDIFICATION MODEL **c76**

Philippe Larroude, Jalil Ouazzani (Alabama Univ., Birmingham.), and J. Iwan D. Alexander (Alabama Univ., Birmingham.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 533-538 Sponsored by NASA, Washington; Alabama Supercomputer Network; Alabama Univ.; CNES; and Inst. Mediterraneen de Technologie (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Flow transitions in a Two Dimensional (2D) model of crystal growth were examined using the Bridgman-Stockbarger me thod. Using a pseudo-spectral Chebyshev collocation method, the governing equations yield solutions which exhibit a symmetry breaking flow tansition and oscillatory behavior indicative of a Hopf bifurcation at higher values of Ra. The results are discussed from fluid dynamic viewpoint, and broader implications for process models are also addressed. ESA

TEXUS 28 EXPERIMENT: CONVECTIONS AND CRYSTAL GROWTH OF Ge:Ga. ANALYSIS OF TEMPERATURE MEASUREMENTS **c76**

Uwe Moeller, B. O. Hildmann, and G. Baehr *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 539-543 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A TEXUS sounding rocket experiment in which a Ga doped germanium crystal was directionally solidified under different acceleration states is presented. The solidification process was started on Earth (1g) and was continued during lift off of the rocket (up to 12g) and the microgravity period (0.0001g) until the reentry phase. The aim of this experiment was to analyze the effects of resulting convections in the melt on the grown crystal. For characterization of the different convectional states, temperatures were measured with three thermocouples at different positions in the melt. An analysis of the thermocouple data is presented. The results are compared to corresponding experiments in the Earth laboratory. The temperatures signals measured in the melt can be assigned to the different acceleration states during the flight. The fast Fourier transform analyses of these signals on Earth, and under microgravity conditions, show that low frequent disturbances up to 0.3 Hz are more pronounced under 1g than under microgravity. Whereas frequencies at about 1.1 Hz are more pronounced under microgravity than under 1g. The measured axial concentration profile agrees well with model calculations known from literature. ESA

TEM STUDY OF A SPACE PROCESSED Al-Al2O3 METALLIC COMPOSITE **c24**

H. Zou (Wuhan Univ., China.), L. Froyen, L. Delaey, and A. Deruyttere *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 549-554 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The microstructure of space processed Al-Al2O3 metallic composite was studied with Transmission Electron Microscopy (TEM) and compared with the microstructures of the starting material and the material remelted on Earth. The alumina particles are flat, ellipsoid-like, and have dimensions of about 0.2 micrometers in diameter and about 0.03 micrometers in thickness. The alumina particle agglomerates distribute densely in bands in the starting material. No significant difference in the distribution of particles was found between the samples that were liquid phase processed in space and those processed on Earth. No sedimentation of particles in the material remelted on Earth was observed. These findings are explained in terms of Brownian motion. The alumina particles are identified with electron diffraction mainly as gamma alumina. After remelting at 800 C for 3 minutes, a few alpha alumina particles were observed. A crystallographic relationship between gamma and alpha alumina was found with electron microscopy. ESA

IN SITU OBSERVATION OF TEMPERATURE DEPENDENCE OF CONCENTRATION FIELD DURING GROWTH OF KB5 CRYSTALS BY HOLOGRAPHIC INTERFEROMETRY **c76**

W. C. Chen, Y. X. Shen, and M. Y. Ma *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 555-558 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The growth of potassium pentaborate tetrahydrate crystals was studied by both gel and low temperature solution methods for simulation of crystal growth in space. A set of in situ experiments concerning the temperature dependence of KB5 crystal growth were carried out by holographic interferometry. The experimental results showed that the concentration distribution during cooling is quite different than that in heating, and that, the influence of temperature on the concentration of KB5 in a free solution is more sensitive than that in the gelled medium. The findings will benefit the design of the facility which could be used for crystal growth in space and on the Earth. ESA

PULSATILE INSTABILITY IN RAPID DIRECTIONAL SOLIDIFICATION: STRONGLY-NONLINEAR ANALYSIS **c76**

Richard J. Braun, G. J. Merchant (Stanford Univ., CA.), K. Brattkus (California Inst. of Tech., Pasadena.), and S. H. Davis (Northwestern Univ., Evanston, IL.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 559-562 Sponsored by NASA, Washington (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

In models of rapid directional solidification, non-equilibrium interfacial conditions are employed. As a result, there is an oscillatory mode of instability, as well as the steady cellular mode, found in the equilibrium model of Mullins and Sekerka. When the temperature field is decoupled from the problem, the preferred wave number for the oscillatory mode is zero, and the interface pulsates in time while remaining spatially uniform. Results from multiple scale analyses in the two limiting cases of the parameters are reported. In these limits, it is found that the instability is a bifurcation to relaxation oscillations; these nonlinear oscillations may be related to the observed microstructure that results from rapid solidification processes such as laser surface remelting. The capture of particles during crystal growth, which is determined not only by the crystallization process but also by transport phenomena and the whole complex of surface properties, is considered here in terms of wetting. Conclusive proof of the importance of surface properties in particle engulfing is offered by the experimental investigation of treated and untreated small polyamide spheres ahead of an upward-moving, planar, horizontal ice-water interface. The surface state of the particles is characterized for each experiment by the measurement of the contact angle of a sessile water drop. A clear correlation is established between the contact angle values and the properties of engulfment. For very high angles (approximately 80 deg), the particle is always captured, whereas for low angles, there is a critical velocity of the freezing front below which the particle is rejected. ESA

Recent developments and results relating to specific heat, thermal conductivity, surface tension, and viscosity of undercooled liquid metals are surveyed. Undercooling plays a major role in any solidification process. In fact, it is the driving force for solidification and determines not only the growth velocity, but also phase selection and formation of metastable phases. In this regime, the knowledge of the thermophysical properties, such as specific heat, thermal conductivity, viscosity, is of particular importance. Convective instabilities, nucleation rates, and solidification velocities are all governed by these parameters. With the advent of containerless processing techniques, in particular electromagnetic levitation, it is now possible to study the undercooled melt in situ and apply sophisticated noncontact diagnostics, such as pyrometry and high speed videography. Electromagnetic levitation is especially suited for studying bulk properties of metallic samples. ESA

NEW MECHANISM OF OSTWALD RIPENING IN LORENTZ-FORCE STABILIZED Cu-Pb DISPERSIONS **c76**

Dirk Uffelmann, L. Ratke, W. Bender, and Berndt Feuerbacher *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 585-589 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Measurements and theoretical investigations on Ostwald ripening of Cu particles in a liquid Pb-Cu melt with low volume content of the phase dispersed are presented. For this purpose, a novel technique that is able to suppress sedimentation of particles in an electrically conducting matrix was invented. The experiments on solid-liquid Cu-Pb dispersions in a low volume fraction range, which is not accessible by conventional experimental techniques, reveal the existence of stationary particle size distributions. The particle growth differs significantly from the growth law of the Lifshitz, Slyozov, and Wagner theory (the basic theory for particle coarsening) for diffusion controlled Ostwald ripening indicating that in this system the particle coarsening is not only diffusion limited. A new growth model that is based on the assumption of preferred places for the trapping of Cu atoms at dislocation sites emerging at the particle surface is presented. The new theoretical approach describes the experimental results excellently. ESA

RESULTS OF CRYSTAL GROWTH EXPERIMENTS BY FZM ON ZONA FACILITIES IN MICROGRAVITY

I. V. Barmin, A. V. Egorov, and Alexander S. Senchenkov *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 591-596 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Some results of the experiments on crystal growth by Floating Zone Method (FZM), which were carried out onboard photon satellites, are presented. The description of the ampoule design and the list of the samples used are given. It is shown that heat transfer between a heater and a sample differ in space and on the ground. Consequently, it is insufficient to determine the heater temperature experimentally on Earth, but the theoretical analysis of heat transfer in space and on Earth is indispensable. The data on macro- and microinhomogeneity and dislocation density are presented. The presence of growth striations in the grown crystals testifies to the oscillating regime of the thermocapillary convection. To eliminate this defect, the axial static and rotating magnetic fields are used. ESA

SOLIDIFICATION OF UNDERCOOLED Ni-32.5 WT PERCENT Sn EUTECTIC ALLOY **c26**

L. Q. Xing, D. Q. Zhao, X. C. Chen, X. S. Chen, G. C. Yang (Northwestern Polytechnical Univ., Xian, China.), and Y. H. Zhou (Northwestern Polytechnical Univ., Xian, China.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 597-602 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Bulk Ni-32.5 wt percent Sn eutectic alloy was undercooled by electromagnetic levitation processing. The recoalescence event was observed by using high speed cinematography. The dendrite tip velocities were measured and calculated. The solidification mechanism and the microstructural change from regular eutectic to anomalous eutectic were studied. It was found that the dendrite tip velocity of Ni3Sn phase was greatly larger than that of Ni(alpha) phase, as a result, Ni3Sn dendrites grew primarily into the undercooled melt in a 'dendritic cluster' morphology. The 'dendrite clusters' developed into 'anomalous eutectic' microstructures by ripening of Ni3Sn dendrites and growing of Ni(alpha) phase between the Ni3Sn arms. ESA

UNDERCOOLED W-Re AND Mo-Re DROPS IN AN ULTRA HIGH VACUUM DROP TUBE **c26**

E. Cini, B. Vinet, L. Cortella, and J. Bletry *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 603-607 (For primary document see N94-10171 01-29)

(Contract ESTEC-9638/91/NL/JSC)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Millimetric W-Re and Mo-Re droplets were undercooled and solidified under ultra high vacuum conditions in a 48 m high drop tube. The first observations and experimental results concerning the microstructures and the phases that were obtained are presented. For the most part, the W-Re and Mo-Re droplets exhibited cellular to dendritic microstructures. One solidification velocity was estimated at 3 m/s. Both the observations and the estimation agree with the usual cooling rates measured in high drop tubes under vacuum conditions (about 500 K/s). However, solidification microstructures may be altered during cooling in the solid state (namely by grain coarsening and ripening). The expected contraction of the (W) lattice parameter with the addition of Re was measured. The microstructural features of some W-Re droplets together with porosity measurements suggested two typical solidification regimes for droplets: one with a 'shell' solidification front for small relative undercoolings, and one with a 'quasi-planar' front for large relative undercoolings prior to nucleation. Some results obtained by numerical simulation provided qualitative agreement. Two Mo-Re droplets yielded a supersaturated (Mo) solid solution containing 59 wt. percent (i.e. 43 at. percent) Re. This seems to indicate a compositional metastability, which could be expected from the Mo-Re phase diagram. ESA

NON-EQUILIBRIUM SOLIDIFICATION IN UNDERCOOLED Ni-B ALLOYS **c26**

Klaus Eckler, R. F. Cochrane (Leeds Univ., England.), M. Jurisch (Zentralinstitut fuer Festkoerperphysik und Werkstofforschung, Dresden, German D.R..), D. M. Herlach, and Berndt Feuerbacher *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 609-614 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Dendrite growth velocities were measured as a function of undercooling in droplets of dilute alloys of B in Ni undercooled by up to 306 K using an electromagnetic levitation technique. At a critical undercooling, depending strongly on the B concentration, a steep rise of the dendrite growth velocity was observed. The analysis of the results within current theories of dendrite growth gives evidence for a transition from diffusion limited to purely thermally controlled growth with the consequence of partitionless solidification. The consequences of such a transition were investigated with respect to the microstructure evolution. ESA

The main goal of the Mephisto first flight is the study of the morphological instability of a plane front. The Mephisto space device is the result of a collaboration between the French atomic and space agencies. Operational since 1988, this advanced solidification furnace is scheduled to fly in the Space Shuttle on Sep. 1992. Its main feature consists in following the real solidification interface temperature by means of a thermoelectric measurement. Interesting results already obtained on the ground are presented. The results concern the following topics: macro and micro segregations real time supervision; and check of theoretical models predicting the solute layer extension versus the hydrodynamic state of the liquid bulk. The lessons of the ground experiments and their impact on the flight program are discussed. ESA

EFFECTS OF A MICROGRAVITY ENVIRONMENT ON THE CRYSTALLIZATION OF BIOLOGICAL MACROMOLECULES

Alexander McPherson *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 619-626 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Macromolecules crystals are indispensable intermediates in the analysis of macromolecular structure, are essential for the application of X-ray diffraction methods, and are at the same time the greatest obstacle to success. Protein crystals are generally difficult to grow, often of imperfect form or small size, and frequently lack sufficient order. Their growth has become the rate limiting step in X-ray crystallography. Evidence has emerged from protein crystallization experiments carried out in space that suggest macromolecular crystals of improved order and quality can be grown in a microgravity environment. Presumably the absence of density driven convection and sedimentation permits a more deliberate and graceful entry of individual molecules into the crystal lattice. This in turn results in improvements in both morphology and the diffraction patterns of the crystals. The precise mechanisms for these improvements and the means for their optimization are, however, not understood at more than a rudimentary level. Microgravity effects that may play a role in protein crystal growth, sedimentation, convection and surface contact are reviewed and suggestions as to their possible mechanisms are made. ESA

RIPENING OF IMMISCIBLE LIQUID DROPLETS IN MICROGRAVITY WITH CONSTRAINED MARANGONI DRIFT

S. Goodman and Reginald W. Smith *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 635-640 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

In order to investigate droplet growth phenomena in immiscible alloy systems, experiments are currently being performed with the binary system of aluminum-indium. The experiments are performed during the reduced gravity periods available in parabolic aircraft trajectories and sounding rocket flights. These experiments, as well as ground based work consitute the QUIMAL (Queen's University Experiments in Immiscible Alloys) program. The aim of the program is to restrain Stokes' flow as well as Marangoni convection in order to measure the rate of droplet growth due to Ostwald ripening alone. In order to restrain these forces a small amount of iron is added to the system. Upon cooling the addition of iron results in the nucleation of intermetallic FeAl3 blades prior to the separation of indium droplets. Preliminary experiments aboard NASA's KC-135 have shown that 4 wt percent iron is effective in reducing Marangoni drift. Results of all QUIMAL tests done to date are given and an overview of experiment preparations and hardware design is provided. ESA

CONDUCTIVE-RADIATIVE MODEL FOR PREDICTING THE SHAPE OF HgI2 CRYSTAL GROWN IN THE LTVG FURNACE c76

A. Roux, A. Fedoseyev (Institute of Biomedical Problems, Moscow, USSR.), and Bernard Roux *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 641-644 Sponsored by Conseil Regional PACA (For primary document see N94-10171 01-29)
(Contract ESTEC-8431/89/F/BZ)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The modeling of heat exchanges in a sealed ampoule in the LTVG (Low Temperature Vapor Growth) furnace is focused upon, in order to compute temperature fields and control the growth of HgI2 crystals from vapor phase at low temperatures. A coupled conductive radiative model was used to determine the shape of the source and the crystal at different equilibrium states (that is, without growth rate). The model involves conductivity anisotropy in the crystal and radiative exchanges between grey and diffuse surfaces (source and crystal interfaces, pyrex walls), which are considered as opaque. Internal buoyancy effect is not taken into account as the pressure inside the ampoule is very small. The source temperature is fixed. For different undercoolings, that is, for different cold finger temperatures, the 'equilibrium' isotherm between the source/gas and crystal/gas interfaces was numerically obtained. This 'equilibrium' isotherm, which is associated with the stop of the growing process, gives a crystal shape. This shape is compared with experimental results given by the ETH-Zurich group. The model would permit a better understanding and control of the future HgI2 crystal growth experiment. The computations are performed using a finite element package (FIDAP). ESA

The coarsening of solid cobalt particles in a liquid copper matrix during annealing at 1200C was investigated experimentally using volume fractions of cobalt between 30 and 50 percent. This is possible on Earth, since the density difference between both phases is small. Sedimentation was negligible in the alloys used. The experimental results are compared with the theory of Ostwald ripening for diffusional transport of matter. Generally the experimental results agree well with the theory of Voorhees and Glicksman. At higher volume concentrations and after long coarsening times there are small but significant differences between the theoretical predictions and the experimental results. They indicate that experiments under microgravity conditions would be needed to extend the range of volume fractions down to a few percent which would be desirable theoretically, and to suppress all effects stemming from buoyancy. EFFECT OF EXPERIMENTAL PROCEDURE ON PATTERN FORMATION AND ARRAY DISORDER IN CELLULAR SOLIDIFICATION c76

Henri Nguyen Thi, Haik Jamgotchian, and B. Billia *In* ESA, Proceedings

of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 651-654 Sponsored by CNES and CNRS (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Cellular arrays in Bridgman directional solidification of Pb-Tl are investigated. By using two different experimental procedures, the response of the planar interface to a sudden change in pulling velocity is examined. It is shown that the final pattern characteristics (average wavelength, level of disorder) are independent of experimental conditions even if the system reaches its steady state by different transients. It is found that in both cases, the solid-liquid front velocity significantly overshoots. ESA

SOLIDIFICATION AND METASTABLE PHASE FORMATION OF HIGHLY UNDERCOOLED Fe-Cr-Ni ALLOY MELTS **c26**
W. Loeser, T. Volkmann (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne, Germany.), and Dieter M. Herlach (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne, Germany.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 655-663 Sponsored by DLR (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Nonequilibrium solidification behavior and the expected phase formation of ferrite (bcc) and austenitic (fcc) primary solidification type Fe-Cr-Ni alloys are theoretically analyzed. Using current theories the nucleation probability and the dendrite growth velocity are investigated as a function of melt undercooling and concentration for both types of the alternative phases. The results of the calculations are compared with measured dendrite growth velocities revealing an agreement between theory and experiment. Microgravity aspects of the experiments are highlighted with respect to an extension of the attainable undercooling towards the hypercooling limit where critical effects are expected to occur in the formation of metastable phases and in the growth behavior. A drop tube providing a free fall time of approximately 0.7 s which is capable of containerless melting and resolidification of small samples with diameters of less than 500 micrometers, is described. Processing can be done in UHV (less than 0.000001 Pa) or in a clean gas atmosphere (He, purity 99.9996 percent). First results on the creation of the intermetallic compound Mn50Bi50 are presented. The system MnBi exhibits a miscibility gap in the liquid. The equiatomic compound of 1:1 stoichiometry is built at 719K by means of a peritectic transformation. As a consequence of the Bi sedimentation Mn is lacking for this peritectic reaction to the gravity of Earth. Thus the final reaction product is a relatively coarse mixture of Mn, Bi and MnBi, the latter having only a portion of less than 20 percent by weight. A way to solve this problem is containerless melting and resolidification in microgravity. ESA

During the directional solidification of succinonitrile-acetone mixtures, acetone bubbles are nucleated in the intercellular grooves. Then bubbles grow with elongated bodies the tip position being a function of the growth parameters and bubble size. Solid envelopes get attached to the bubbles to form duplex structures. The interaction of such localized duplex structures with the solidification front, which depends on the experimental control parameters, was investigated. In the beginning of the cellular range, finite amplitude cells are observed only a distance from the bubbles. At higher acetone concentration, highly correlated sidebranches appear and amplify on the duplex structure, which means that a duplex structure can undergo an oscillatory dendritic transition. ESA

LIQUID PHASE SINTERING OF TUNGSTEN COMPOSITES UNDER MICROGRAVITY. EFFECT OF MATRIX COMPOSITION
Lars B. Ekbom and A. Eliasson *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 673-678 Sponsored by ESA and Swedish Board for Space Activities (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Tungsten heavy metals containing 90 to 95 percent W, Ni and Fe, were produced from powders by liquid phase sintering. The resulting composite consists of tungsten particles in a Ni-Fe-W-matrix. Eight different compositions were studied. TEXUS flights (10, 19, 26, 27) and parabolic flights were used for liquid phase sintering microgravity experiments. Liquid phase sintering includes a liquid penetration of agglomerates and tungsten particle growth. Cobalt was found to facilitate the separation of agglomerates and increases the growth rate. The particle growth rate of a W-Ni-alloy is higher than for the W-Ni-Fe-alloys. Calculations show that the surface energy is 5 times larger for the W-Ni alloy. ESA

EFFECT OF GRAVITY ON THE DISSOLUTION AND LIQUID PHASE EPITAXIAL GROWTH PROCESSES IN A HORIZONTAL SANDWICH SYSTEM
Sadik Dost, S. Erbay, H. A. Erbay, and N. Djilali *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 679-684 Sponsored by Canadian Space Agency (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Results of a numerical study of the dissolution and growth processes of silicon in a sandwich system are presented. The governing equations and the associate boundary and interface conditions of the system under isothermal conditions are given for a nominally two dimensional model. The numerical results for the concentration distribution, the dissolution depth and the growth thickness are in good general agreement with experimental observations. It is concluded that convective effects must be accounted for in order to reproduce experimentally observed features such as differences between the dissolution depths or the growth thicknesses of the upper and lower substrates. Several zeolites were prepared in microgravity conditions during the Casimir 1 flight in Sep. 1990. The effects of reduced gravity on the crystal size, composition and crystallinity of an analcime, mordenite, gismondine and zeolite beta were studied. Microgravity affected crystal size in a significant way in the case of zeolite synthesis from a clear aluminosilicate solution. A lower crystallization rate was observed in microgravity experiments, probably due to a slower mass transfer in the solution. ESA

A STUDY OF THE QUASIBINARY Al-Mo-W SYSTEM. PART 2: A PHYSICO-MECHANICAL INVESTIGATION OF THE SYSTEM FABRICATED UNDER THE GRAVITYLESSNESS CONDITIONS
Stavri Stavrev and V. Atanasova *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 699-702 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The investigation of a quasibinary Al-W-Mo system formed under weightlessness conditions at different temperature gradients are described. The samples were fabricated using the onboard 'Yantar 2' crystallization plant on board the Space Station Mir. Such methods as X-ray, SEM (Scanning Electron Microscopy), microprobe, metallographic microscopy and chemical analysis were used to estimate conditions necessary for fabrication of this promising composite. It was found that the greater temperature gradient (greater overcooling) results in more homogeneous and fine structure of the composite. ESA

The resistivity heater ZMF was developed to examine the influence of the temperature gradient on crystal growth. The ZMF in the present configuration is described. It is a ten zone resistance heater for growth experiments by the Travelling Heater Method (THM). The furnace is built up as a modular crystal growth facility for accommodation onboard of Spacelab and Space Station Freedom. One advantage of the furnace is the possibility to change the temperature gradient at the phase boundaries over a wide range. Temperature characteristics of the furnace are specified, which show a high accuracy of the temperature field. Growth experiments are described and the results confirm the appropriate heater concept. Single crystals in the II-VI semiconductor CdTe and of the ternary compound (Al,Ga)Sb with the size of one inch in the diamater and a length of 28 mm are grown. ESA

In relation with microgravity experiments, numerical simulations of pure Marangoni flows in binary mixtures are presented. The concentration gradient is induced via Soret effect by the heat flux applied across the layer. The simulations are performed in large two dimensional cavities for slightly supercritical situations. They concern steady situations (pure thermal flows or with a destabilizing concentration contribution), as well as oscillatory situations (stabilizing concentration contribution). The results are analyzed through symmetry considerations and flow characterizations. ESA

Theoretical and experimental analyses of the coupling between thermogravitational and thermocapillary instabilities in pure liquids are presented. Focus is on transient effects appearing in horizontal liquid layers open to an inert gas, and submitted to heat fluxes several times higher than the critical heat flux necessary to induce convection. In this case, infinitesimal perturbations are amplified and evolve towards a stationary convective state. It is shown that this can happen through a process of damped oscillations, especially when gravity induced convection plays the dominating role, or when the injected heat flux is high enough (which is shown to be equivalent). This is explained by the creation of a stabilizing thermal gradient in the bulk of the liquid, where the buoyancy force acts. Experiments also show the possibility to correlate the relative phase displacement between mean temperature drop and mean surface velocity curves, with the ratio between the driving forces. This is qualitatively confirmed by the initial conditions approach. The limits of velocity of the classical frozen time linear stability method, are also discussed and compared with the initial conditions method. ESA

The study of the Marangoni-Benard and Rayleigh-Benard instability is extended to a system of three superposed immiscible layers submitted to an external temperature gradient perpendicular to the free interfaces. Under microgravity conditions, a symmetrical system consisting of a fluid A sandwiched between two layers of a fluid B is considered. The crucial role of diffusivity ratio (kappa = kappa(sub B)/kappa(sub A) on the kind of instability is shown. When the thermal diffusivities are very different (kappa not equal to 1), monotonous mode of instability driven by one interface is observed. When kappa is close to one, the monotonous critical Marangoni number becomes infinite and an overstable solution results from the coupling of both interfaces as a flip-flop oscillating mechanism. An experimental three layer was then taken, consisting of Fluorinert FC70, Silicone Oil 50 CS and air which is stable with respect to the density on ground. Different instability mechanisms were recorded. For moderate values of the Rayleigh number, the threshold of instability depends on the value of Marangoni number only, when the Rayleigh number is increased both thermocapillary and gravitational mechanisms collaborate, reminiscent of the famous Nield's theory. For pure thermocapillary convection, mechanical coupling between the layers can exist, and the appearance of thermal coupling for gravitational convection is explained in term of a nonlinear coupling. ESA

INSTABILITY OF THERMOCAPILLARY CONVECTION IN MULTIPLE SUPERPOSED IMMISCIBLE LIQUID LAYERS c34

Q. S. Liu and Bernard Roux *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 735-740 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The linear and nonlinear instabilities analyses of multiple (two or three) immiscible liquid layers heated from below under microgravity conditions was studied by means of small perturbation method and a finite difference method, respectively. The lower wall is considered as a rigid perfectly conducting boundary. Either rigid or free top surface and planar interfaces are considered. The mode of instability is induced purely by surface tension gradient at each of the two or three interfaces (liquid-liquid and liquid-air). This may have application in space experiments. Marangoni-Benard instability in a three layer system in gravitational field is also studied. ESA

The influence of high frequency linear polarized vibrations of the plane liquid layer or liquid cylinder on Marangoni convection developed due to a temperature gradient is considered. Situations which may give rise to thermocapillary parallel closed flows in a liquid layer subject to harmonic high frequency vibrations are examined. The layer is bounded by cylindrical or plane interfaces. In case of a plane layer one or both boundaries are assumed to be free and vibration has arbitrary orientation. For liquid cylinder vibrations are supposed longitudinal. The flow is described by the averaged equations of convection. The flow structure and its intensity depend on three dimensionless parameters: Marangoni, q and Q numbers which define longitudinal and inclined vibration effects. It is shown that intensity of convective flow may be effectively controlled by an appropriate choice of vibration parameters. ESA

APPEARANCE OF CONVECTIVE INSTABILITIES CAUSED BY LIQUID-LIQUID PHASE SEPARATION UNDER SMALL BUOYANCY FORCES c34

Roland Zander and G. M. Schneider *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 755-759 Sponsored by BMFT (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The far critical liquid-liquid phase decomposition that is induced in a horizontal fluid layer being exposed to a vertical temperature gradient and which can generate dissipative structures is investigated during ground based experiments using samples of near isopycnic components. The dissipative structures generated appear as a bulk fluid convection that is closely related to the two component Rayleigh-Benard instability. The convection is mainly driven by the concentration gradient which occurs in consequence of the demixing under the influence of the temperature gradient. Because comparatively small buoyancy forces are sufficient to trigger the instability, it is expected to appear also under reduced gravity down to an order of magnitude that is in praxi about 0.00001 g. Additionally, even in the presence of gradients which do not suffice to support such a bulk liquid convection, a regular organization of the floating precipitate is found. This phenomenon could result from an instability of the two phase liquid layer that is caused by the Marangoni driven migration of the droplets. ESA

THE COMBINED INFLUENCE OF ANTICONVECTIVE AND THERMOCAPILLARY MECHANISMS ON THE STABILITY OF SYSTEMS WITH INTERFACE c34

Illya B. Simanovskii, Alexander A. Nepomnyashchy (Technion - Israel Inst. of Tech., Haifa.), P. Colinet (Brussels Univ., Belgium.), J.-C. Legros (Brussels Univ., Belgium.), and Stefan VanVaerenbergh (Brussels Univ., Belgium.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 767-770 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A theoretical analysis of the combined influence of anticonvective and thermocapillary mechanisms in a two layer system is presented. The lower fluid has a significantly larger value of heat diffusivity than the upper one, and the upper fluid gas a significantly lower value of heat expansion coefficient than the lower one. These are necessary conditions for the anticonvective mechanisms to manifest, when heating the system from above. Both linear and nonlinear situations are analyzed. Linearly, the threshold value of the Grashoff number across the layers is foreseen to decrease with the increasing effect of destabilizing Marangoni-Benard mechanism. In the nonlinear case, when both mechanisms are destabilizing, numerical simulations predict multiple stationary solutions, which can be obtained starting from different initial conditions. ESA

INFLUENCE OF NEUTRAL PARTICLES CONCENTRATION ON FLAME PROPAGATION IN METHANE-AIR MIXTURES AT ZERO AND NORMAL GRAVITY CONDITIONS

M. M. Gieras *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 773-777 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Results of investigation of flame propagation and extinction in methane-air mixtures in the presence of chemically neutral particles are presented. Standard vertical tube 1.2 m long and square cross section 0.05 by 0.05 sq m was used in the tests. The experiments were conducted at normal gravity and microgravity conditions, using a special stand. Profiles of velocity, temperature and thickness of flame front as well as changes in the flame structure in relation to methane and neutral particles concentration were determined. The experiments allowed conditions at which addition of neutral particles could cause extinction or acceleration of flame to also be determined. It was indicated that particles cause development of microturbulence and intensify combustion process by increase of burning surfaces and by increase of heat exchange by radiation. ESA

GRAVITY AND ELECTRIC FIELD EFFECTS ON POOL BOILING HEAT TRANSFER

W. Grassi and Paolo DiMarco *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 783-788 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A review was carried out to investigate the effects of gravity and electric fields on pool boiling heat transfer. The electric field proved to enhance the boiling performance in on Earth applications. In absence of gravity, phenomena generally neglected in Earth theories, may have a fundamental role in the boiling process. Besides, the boiling crisis is probably not governed by the hydrodynamic instability in such conditions. As far as known, the effect of an electic field on boiling in microgravity has never been investigated experimentally. The main features of the pool boiling heat transfer with and without an imposed electric field, and the expected modifications in a microgravity environment, are stressed. The areas in which further investigation and experimentation is needed are reported. An experimental campaign in microgravity conditions is expected to yield advances both in the understanding of the basic boiling mechanisms and in space heat transfer applications. ESA

Chemical structures which arise spontaneously on a macroscopic scale in certain reaction systems with autocatalytic steps evolving far from thermodynamic equilibrium are considered. In these systems, symmetry is broken as a consequence of the nonlinear coupling of chemical kinetics with transport processes such as diffusion or convection. Interesting applications lie in the understanding of pattern formation in biology. The formation and dynamics of the patterns depend delicately on the precise experimental conditions. They can be disturbed by sedimentation which, under normal gravity, can be caused by global and local heat production by the reaction itself. Regular and irregular structure formation is illustrated for a few examples and the relevance of microgravity research is substantiated by proposing several ideas for microgravity experiments. ESA

The adsorption behavior of a near critical fluid (sulfur hexafluoride) on a graphitized carbon black (V3G) and in Controlled Pore Glasses (CPG-10) was studied. The surface excess amount Gamma of SF6 on V3G was measured by approaching the critical point along the critical isochor from the one phase region using a new volumetric technique. Results of experiments to investigate the critical behavior of SF6 in narrow pores (CPG-10) of mean pore diameters 7.7 nm and 24.2 nm are also reported. ESA

The instabilities induced by gravity on the interface separating two fluids of different densities (Rayleigh-Taylor instability), one of the two fluids being confined in a thin layer spread on a solid surface, is studied. In the simplest geometry (liquid films hanging below solid surfaces, the second fluid being a gas), pattern formations in two dimensions are observed involving competition between different symmetries, front propagation phenomena, nonlinear pattern selection, etc. When the unstable film is continuously supplied with 'fresh' liquid by an external source, different regimes of liquid emission are observed: periodic arrays of dripping sites, periodic arrays of liquid columns, and liquid sheets. The arrays of liquid columns exhibit a spatiotemporal behavior suggesting a possible transition towards chaos (oscillations, wave propagation, pairing or nucleation of cells, etc.). ESA

In order to investigate some aspects of heat and mass transport in fluids in the absence of gravity, thermal cycles were performed near the liquid-phase critical point of CO2 and SF6 in the TEXUS 25 rocket and during the International Microgravity Laboratory (IML-1) Spacelab mission. In the absence of gravity driven convection, the heat transport is expected to be diffusive and very slow. Experimentally, although the local density and temperature gradients indeed relax by a diffusive process, clear evidence is found of fast and uniform thermal equilibration. This new mechanism is a 'piston effect'. ESA

Details of the experiment TES (German acronym for thermodynamic properties of undercooled melts) and the developed experiment hardware equipment are given. TES is scheduled for flight on the German-Russian mission Mir '92, and is aimed at the determination of the heat capacity of undercooled metals and alloys. It is realized by two probes, which will be processed in the furnace CSK-1, and by a dedicated data acquisition unit. A differentional method is applied comparing the thermal behavior of the sample under study with that of a reference sample of well known properties. The experimental device allows the measurement of absolute temperatures within the range 0 to 1000 C with a resolution of 0.25 K and of temperature differences with a resolution of 2.5 mK. It is noted that the thermophysical data of metallic melts are fundamental in characterizing the liquid state and analyzing the thermodynamics and kinetics of the liquid-solid phase transition. Within the regime of the undercooled melt, the heat capacity as the most important property is generally not available. ESA

Preparation experiments performed in laboratory and during parabolic flights for a major experiment in nucleation, bubble growth, interfacial phenomena, and evaporation/condensation kinetics forseen for BDPU on the International Microgravity Laboratory (IML-2) are presented. The intention was to get first scientific results and to reduce the technological uncertainties on the development of the BDPU test container. The process starts at a high system pressure to deactivate the nuclei at the walls of a test cell. The pressure is reduced below saturation by a quasi-isothermal expansion. The bubble growth is initiated by a short heating pulse of a thermistor in the liquid. The volume of the growing bubble is compensated by a pressure control system. After this cycle, the pressure is increased again and recondensation is observed. The test of the experimental set up was successful. Only small vapor bubbles can be observed under normal gravity, under reduced gravity<; however, vapor bubbles up to 1 cm in diameter can be produced. Nevertheless, the system is very sensitive to gravity disturbances. ESA

For different particle diameters arranged in a gas fluidized bed, a new gravitational instability is predicted. The first order stability analysis yields conditions for growth of the most unstable wavenumber both as a function of particle diameter and dimensionless Bond number. Gravity acts to distribute the greater fluid mass associated with smaller particles, while surface tension stabilizes the entire bed against accelerations. The phenomenon, called the 'Small-over-Large' (SL) instability, evolves somewhat akin to a Rayleigh-Taylor mechanism and in addition to fundamental interest, carries implications for predicting solute redistribution and gravitational alignments in particle beds and chemical separation columns. A microgravity experiment to study the growth of dust particles which has been proposed to be flown on one of the Columbus precursor flights is described. The microgravity environment will allow for low collision velocities (of order of mm/s) of the dust grains and for a large Knudsen number of the embedding gas; conditions expected in the early solar nebula. The outcome of the experiment will yield estimates of the sticking efficiency and the critical velocity for agglomeration. The values of these two parameters will provide substantial improvements in the constraints for models of the formation of planetesimals. In particular, the questions related to growth rate and mode of the aggregation process will be answered. The range of material type, collision velocities, properties of the environment in which growth takes place, and other factors permit a natural extension of this experiment to take advantage of the capabilities of the Space Station Columbus. Other astrophysical applications, such as processes in Saturnian rings, with somewhat different regimes could also be investigated. ESA

The preparation and characterization of an aluminum Metal Matrix Composite (MMC) reinforced with Ni3Al rapidly solidified intermetallic ribbons prepared with melt spinning technique is considered. The manufacturing of these composites presents some difficulties for the high reactivity between matrix and intermetallic and their different density. For this reason a space manufacturing is proposed. With the purpose of studying chemical reactions at the interface and preparing a reference material, ground experiments were performed. They confirm the high reactivity of this system and the difficulties in obtaining a homogeneous dispersion in a short time. Preliminary mechanical tests show an almost ductile behavior of this composite. ESA

THE REACTION BETWEEN TITANIUM CARBIDE AND ALUMINIUM CARBIDE IN LIQUID ALUMINIUM; A MICROGRAVITY STUDY

Anders E. W. Jarfors and Hasse Fredriksson *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 849-854 Sponsored by Swedish Board for Space Activities (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The reaction between aluminum carbide and liquid aluminum containing titanium was studied in normal gravity and microgravity. Microgravity was obtained using parabolic aircraft flights. The temperature-time cycle for both normal gravity and microgravity were similar, the samples were preheated to 873 K during a 1.8 g phase and melt when g levels were well below 0.1 g. The heat treatment in liquid state was done at three different temperatures 973, 1173, and 1373 K. A rapid quenching was obtained using a jet of air. Two samples of different composition, one aluminum alloy containing titanium and one aluminum alloy containing carbon, were brought together in the liquid state. Diffusion of titanium and carbon was established. The precipitation process of titanium carbide and the dissolution of aluminum carbide was analyzed. ESA

THE KINEMATICS OF BUOYANCY INDUCED MIXING c34

Walter M. B. Duval *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 855-861 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

A model problem to study mixing driven by buoyancy flow fields due to a time dependent body force which consists of a steady and an oscillatory component is considered. Flow fields generated by a time dependent body force, which consists of a steady and an oscillatory component from vibrations or g-jitter, mix two fluids inside a cavity by stretching and folding the interface into various morphological patterns. These patterns show two basic structures depending on the dominant components of the body force. These structures are whirls and tendrils, corresponding to the dominance of either the steady or oscillatory component, respectively. A combination of these structures also occurs in the interaction region. In this region the effect of the steady component opposes the oscillatory component and the result is to smooth the interface, and prevent breakup of the interface. For the parametric range considered, two basic flow regimes occur: convective and chaotic. In the convective regime, the morphological patterns are topological. In the chaotic regime, mixing occurs by a repetitive sequence of bubble formation, necking, and breakup which spreads the concentration field throughout the cavity. The length stretch of the interface increases exponentially with time. The dynamical system characteristics show that in the convective regime, at a point in space, the flow field is oscillatory with elliptical phase space trajectories, and its power spectrum indicates that the flow field responds to the corresponding input frequency. Whereas, in the chaotic regime, the flow field is aperiodic, the phase space trajectories show irregular patterns, and the power spectrum shows a broadband distribution. ESA

INFLUENCE OF GRAVITY AND AMBIENT PRESSURE VARIATIONS ON THE BEHAVIOR OF BUOYANT LAMINAR DIFFUSION FLAMES

Daniel Durox, Tao Yuan, and E. Villermaux (Grenoble-1 Univ., France.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 863-868 (For primary document see N94-10171 01-29)
Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The buoyant laminar diffusion flames were studied theoretically and experimentally to observe the flame dynamic behaviors as global shape and flame flickering in function of gravity and ambient pressure. The mechanisms of gravity effects and ambient pressure effects acting on these flame behaviors are discussed. The apparent power laws of flame surface for steady flames and of flame flickering frequency for oscillating flames as a function of gravity and ambient pressure were theoretically predicted; the experimental results for these power laws as functions of ambient pressures are in a good agreement with the theoretical predictions. The experiments also showed that both for diffusion flames and premixed flames, the flame flickering frequencies are in the same order of absolute value and possess the same power law as a function of ambient pressure. LASER COOLING AND TRAPPING OF ATOMS IN MICROGRAVITY: ULTRACOLD ATOMS COLLISIONS

Carlo Albanese, Raimond Fortezza, M. Inguscio (Florence Univ., Italy.), and G. M. Tino (Naples Univ., Italy.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 869-871 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

An experiment to investigate the collisional processes in molasses, such as collisions between cold atoms and cold atom surface interactions, in a drastically simplified environment in which the effect of gravity is negligible, is proposed. One of the most interesting areas in the contemporary physical research involves the investigation on atoms and ions in conditions of controlled density, position, and velocity. An outstanding interest is dedicated to atoms slowing down by laser radiation pressure and their localization by magnetic and optical traps. But, the gravitational force in Earth based laboratories reduces the observation time during the experiment, as the slowed atoms fall down out of the region of observation. So a privileged environment for the research on atom trapping by laser radiation pressure is the microgravitational one. Due to the development of diode laser technology, the drawbacks present on Earth may be divided and a very compact experimental facility may be obtained to perform the experiments in a space laboratory. Attention is given to the compactness and energy requisites of the facility and to the possibility of telescience utilization. ESA

USE OF INERT IMMISCIBLE LIQUID FOR CRYSTAL SEPARATION OUT OF ITS FEEDING SOLUTION IN WEIGHTLESSNESS

A. A. Vedernikov, Patrick Queeckers (Brussels Univ., Belgium.), and J. C. Legros (Brussels Univ., Belgium.) *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 873-878 (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The theory behind the use of an inert immiscible liquid for crystal separation out of its feeding solution in weightlessness is discussed. Experiments to test this procedure are described. The preservation of monocrystals after production in microgravity could be reached by pushing away slowly the feeding solution out of the cell. The introduction of an inert liquid leads to the formation of a bridge with two contact lines: one on the inner side of the cell and the other on the crystal. The bridge evolution is analyzed in the framework of quasistationary motion of equilibrium surfaces and compared with the results of separation simulations using two isodense immiscible liquids. Numerical analysis revealed a wide range of parameters for which an increasing liquid volume does not lead to the motion of contact line on the crystal in the direction of its tip. Hysteresis of both contact angles plays an important role in evolution of liquid-liquid interface. ESA

SINGLE BUBBLE EXPERIMENTS IN POOL BOILING: RESULTS FROM TEXUS 26

Bernd Vogel and Johannes Straub *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 879-886 Sponsored by Deutsche Agentur fuer Raumfahrtangelegenheiten G.m.b.H. (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A02/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Single bubble experiments performed on a TEXUS flight to investigate heat transport mechanisms in pool boiling are described. During the series of experiment runs in subcooled boiling, data about bubble growth, heater temperature distributions, and temperature profiles close to the bubble were gained and evaluated. As a result, it can be stated that the main heat transport mechanism is evaporation at the heater wall. Condensation together with Marangoni flow serve as secondary mechanisms for the heat transport from the vapor bubble further on into the bulk liquid. ESA

A METHOD FOR DETERMINATION OF THE ELONGATIONAL VISCOSITY OF VISCOELASTIC FLUIDS WITHOUT BODY FORCES c34

S. Berg, A. Delgado, R. Kroeger, and Hans J. Rath *In* ESA, Proceedings of the 8th European Symposium on Materials and Fluid Sciences in Microgravity, Volume 2 Aug. 1992 p 901-904 Sponsored by BMFT and the Senator for Education and Arts of the State of Bremen (For primary document see N94-10171 01-29)

Copyright Avail: CASI HC A01/MF A04; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The elongational viscosity of elastic fluids depends on the actual elongation stress as well as on the stress history. In order to perform an accurate determination of the elongational viscosity of polymer liquids, a pure extensional flow with a constant strain rate and a zero stress history is required. Both requirements can not be provided under terrestrial conditions but under conditions of microgravity. For this purpose a new experimental set up was developed, which realizes the classical tension experiment under conditions of microgravity but fluids are used as the sample. An arrangement like this enables the direct measurement of the arising elastic forces during extension of the fluid bridge. However, this leads to significant requirements of fluid management, especially because the experimental set up is designed for short time operation in drop tower facilities. ESA

Experiments in constant volume combustion of dust in air in a 4 liter spherical vessel were carried out in 1 g and microgravity environments. The diagnostics involved exclusively piezoelectric pressure transducers to measure the pressure-time history of the combustion process. Different delay times between dust dispersion and ignition were generated to assess the effect of dispersion turbulence on the combustion process. Highest pressures were achieved with delay times of the order of 200 ms in both the 1 g and microgravity experiments. This peak pressure was of the order of the theoretically calculated constant volume pressure (approximately 12 bar). In the 1 g case, the peak combustion pressure decreased to nothing as the delay times approached 600 ms. For microgravity experiments, long delay times (up to 20 sec) could be generated. The peak pressure asymptotically levelled out to about 4 bar (one third of peak constant volume pressure) for delay times larger than about 600 ms. ESA

The material science experiments performed on the International Microgravity Laboratory (IML-1), which is used to perform investigations which require the low gravity environment of space, are discussed. These experiments, the principal investigator, and associated organization are listed. Whether the experiment was a new development or was carried on an earlier space mission, such as the third Spacelab (SL-3) or the Shuttle Middeck, is also noted. The two major disciplines of materials science represented on IML-1 were the growth of crystals from the melt, solution, or vapor and the study of fluids (liquids and gases) in a reduced gravity environment. The various facilities on board IML-1 and their related experiments are described. The facilities include the Fluids Experiment System (FES) Vapor Crystal Growth System (VCGS) Organic Crystal Growth Facility (OCGF), Cryostat (CRY), and the Critical Point Facility (CPF). ESA

The application of an AC (Alternate Current) electric field to a mercury drop resulted in large-amplitude shape oscillations due to variations in its surface tension. Quasi-two-dimensional (2-D) oscillation patterns were identified from the 2nd to 16th modes for flattened drops under a pressure of 1 G. In addition, three dimensional oscillations were observed in low-gravity using a drop tower, with several polyhedra patterns being clearly identified, e.g., a tetrahedron, hexahedron, octahedron, and dodecahedron. PROJECT ARGO: GAS PHASE FORMATION IN SIMULATED MICROGRAVITY
Michael R. Powell, James M. Waligora, William T. Norfleet, and K. Vasantha Kumar (Krug Life Sciences, Inc., Houston, TX.) Jul. 1993 96 p
(NASA-TM-104762; S-711; NAS 1.15:104762) Avail: CASI HC A05/MF A01

The ARGO study investigated the reduced incidence of joint pain decompression sickness (DCS) encountered in microgravity as compared with an expected incidence of joint pain DCS experienced by test subjects in Earth-based laboratories (unit gravity) with similar protocols. Individuals who are decompressed from saturated conditions usually acquire joint pain DCS in the lower extremities. Our hypothesis is that the incidence of joint pain DCS can be limited by a significant reduction in the tissue gas micronuclei formed by stress-assisted nucleation. Reductions in dynamic and kinetic stresses in vivo are linked to hypokinetic and adynamic conditions of individuals in zero g. We employed the Doppler ultrasound bubble detection technique in simulated microgravity studies to determine quantitatively the degree of gas phase formation in the upper and lower extremities of test subjects during decompression. We found no evidence of right-to-left shunting through pulmonary vasculature. The volume of gas bubble following decompression was examined and compared with the number following saline contrast injection. From this, we predict a reduced incidence of DCS on orbit, although the incidence of predicted mild DCS still remains larger than that encountered on orbit. Author (revised)

REDUCED GRAVITY MULTIBODY DYNAMICS TESTING Final Report
Meija Sillanpaa 30 Jun. 1993 3 p
(Contract NAS8-39131)
(NASA-CR-192589; NAS 1.26:192589) Avail: CASI HC A01/MF A01

The Final Report on reduced gravity multibody dynamics testing is presented. Tests were conducted on board the NASA KC-135 RGA in Houston, Texas. The objective was to analyze the effects of large angle rotations on flexible, multi-segmented structures. The flight experiment was conducted to provide data which will be compared to the data gathered from ground tests of the same configurations. The flight and ground tested data will be used to validate the TREETOPS software, software which models dynamic multibody systems, and other multibody codes. The flight experiment consisted of seven complete flights on board the KC-135 RGA during two one-week periods. The first period of testing was 4-9 Apr. 1993. The second period of testing was 13-18 Jun. 1993. CASI

MATERIAL REMOVAL PROCESSES: ENGINEERING MECHANICS CONSIDERATION
C. A. Anderson 1993 6 p Presented at the 1993 ASPE Spring Topical Meeting, Tucson, AZ, 13-15 Apr. 1993
(Contract W-7405-eng-36)
(DE93-010733; LA-UR-93-1025; CONF-9304106-2) Avail: CASI HC A02/MF A01

In the material removal process called machining, a layer of material of constant thickness is removed from the workpiece by a wedge-shaped tool that travels parallel to the workpiece at a preselected depth. Even though the speed of relative movement between workpiece and tool is low (typical 1-10 m/s), the strain-rates in the workpiece near the tool can be high, on the order of 10(exp 4)-10(exp 5) /s. When machining brittle materials or unlubricated ductile materials at low speed, the removed metal (or chip) will be discontinuous and made up of small fractured segments. On the other hand, when machining ductile material under lubricated conditions, the removed material forms a continuous coil. In this case, we can represent the material removal process as a steady-state process. In this presentation, we will restrict ourselves to orthogonal machining where the cutting edge is perpendicular to the relative motion--a situation also approximated by other material removal processes such as planing and broaching, and turning on a lathe. Paint stripping and repainting of aircraft surfaces are required periodically during the operating lifetime of an aircraft. Historically, paint removal has been achieved with chemical strippers. These materials often contain toxic components and create hazardous working conditions. It is necessary to ensure that alternate paint removal techniques are available that can be performed in a cost effective, environmentally safe manner without causing damage to aircraft surfaces. For individual titles, see N94-10614 through N94-10629.

Use of methylene chloride and phenol based chemical strippers for aircraft paint removal generates large quantities of hazardous waste and creates health and safety problems for operating personnel. This paper presents an overview of the U.S. Navy's activities in the investigation and implementation of alternate paint stripping methods which will minimize or eliminate hazardous waste and provide a safe operating environment. Alternate paint removal methods under investigation by the Navy at the present time include use of non-hazardous chemical paint removers, xenon flashlamp/CO2 pellets, lasers and plastic media. Plastic media blasting represents a mature technology in current usage for aircraft paint stripping and is being investigated for determination of its effects on Navy composite aircraft configurations. Paint removal activities currently under way in Canada include: research and development of laser paint stripping; development and commercialization of a new blasting medium based on wheat starch; commercialization of a new blasting medium and process using crystalline ice blasting for paint removal and surface cleaning; and the development of automated and robotic systems for paint stripping applications. A specification for plastic media blasting (PMB) of aircraft and aircraft components is currently being drafted by NDHQ for use by the Canadian Armed Forces (CAF) and contractors involved in coating removal for the CAF. Defense Research Establishment Pacific (DREP) is studying the effects of various blast media on coating removal rates, and minimizing the possibility of damage to substrates other than aluminum such as graphite epoxy composite and Kevlar. The effects of plastic media blasting on liquid penetrant detection of fatigue cracks is also under investigation. Author (revised)

OPERATIONAL ASPECTS OF F.16 PLASTIC MEDIA BLASTING, AS CARRIED OUT BY FOKKER AIRCRAFT SERVICES
Frank Pot *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Mar. 1993 3 p (For primary document see N94-10613 01-31)
Copyright Avail: CASI HC A01/MF A02

In 1987, Fokker Aircraft Services started F.16 air-intake paint removal by means of Plastic Media Blasting (PMB). Especially for this process, a robot has been developed. In a later stage, complete exterior PMB-paint removal has been tested and successfully adopted. The paint removal is carried out in the scope of a thorough corrosion control program. The requirement that all the paint must be removed in order to allow this control program to be carried out properly, leads to severe masking complications. The process parameters are relatively conservative, because of the requirement that absolutely no anodic layer damage is permitted. Following PMB paint removal, corrosion is removed using aluminum oxide blasting. Finally, a highly flexible polyurethane paint system is applied, based upon TT-P-2760 Koroflex primer. To summarize the process, it can be stated that the plastic media blasting itself is straightforward. Proper masking is difficult to perform though, compounded by special customer requirements such as open panel edges. Author (revised)

USE OF ROBOTS FOR AIRCRAFT DRY STRIPPING VIA PLASTIC MEDIA BLASTING

E. Gillard *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Mar. 1993 6 p (For primary document see N94-10613 01-31)

Copyright Avail: CASI HC A02/MF A02

In order to meet constant financial and reliability concerns, European manufacturers have introduced more and more composite materials on their aircraft. In addition to fairings for which the use of composites has become absolutely necessary, composites are used on each new program for structures which are more and more highly loaded and sophisticated. Similarly to metallic structures, an external paint scheme is applied to these composite structures to protect them from ultraviolet rays, provide general corrosion resistance and allow the airlines to customize their aircraft. Conventional stripping methods using chemical strippers cannot be used as many impregnation resins do not resist chemical strippers. Aerospatiale has endeavored to find new efficient methods that are easy to implement, cause no damage and are applicable both to metallic and composite structures. Dry stripping via plastic media blasting has formed the subject of many tests. These tests proved that such stripping was compatible with the objectives but required automation of the process for large airframe stripping. Author

German Air Force (GAF) has been researching a method of paint removal for a couple of years to replace the chemical method still in use. This is to improve corrosion prevention, environmental protection and health care. With the support of German aerospace company MBB and the University of the Armed Forces in Munich GAF selected Plastic Media Blasting (PMB) as the most suitable method. Having a stripping facility for the entire aircraft at MBB Manching already in existence, GAF decided that the next step forward to gain more experiences is to establish a smaller 'stripping cabin' at an air force base. This cabin is suitable for stripping removable parts and components of aircraft and equipment with the max. size of a half dismantled TORNADO wing. With these gained experiences GAF will be in position to formulate the specific requirements for an entire on-base aircraft stripping plant which will be suitable for F-4's, TORNADO's and EFA's, too. Hill Air Force Base in Utah developed plastic media blasting (PMB) paint removal process for removing paint from Air Force aircraft. The development of the process involved extensive testing of various abrasives and subsequent parameters to end up with an approved production process. Hill AFB has been using PMB in a production mode since 1985, and completely discontinued chemical stripping of airframes in 1989. We have recently installed and began operating a fully automated PMB facility that utilizes two nine-axis robots to strip an aircraft. This system has enabled us to further reduce the manhours required to strip an aircraft, and also allowed us to remove the employee from the blasting atmosphere into a control room. We have, and will continue to realize, significant environmental and economic savings by using PMB. Hill is also actively involved with the development of future paint stripping technologies. The aircraft maintenance industry is beset by new Environmental Protection Agency (EPA) guidelines on air emissions, Occupational Safety and Health Administration (OSHA) standards, dwindling labor markets, Federal Aviation Administration (FAA) safety guidelines, and increased operating costs. In light of these factors, the USAF's Wright Laboratory Manufacturing Technology Directorate and the Aircraft Division of the Oklahoma City Air Logistics Center initiated a MANTECH/REPTECH effort to automate an alternate paint removal method and eliminate the current manual methylene chloride chemical stripping methods. This paper presents some of the background and history of the LARPS program, describes the LARPS system, documents the projected operational flow, quantifies some of the projected system benefits and describes the High Pressure Water Stripping Process. Certification of an alternative paint removal method to replace the current chemical process is being performed in two phases: Process Optimization and Process Validation. This paper also presents the results of the Process Optimization for metal substrates. Data on the coating removal rate, residual stresses, surface roughness, preliminary process envelopes, and technical plans for process Validation Testing will be discussed. Author (revised)

AUTOMATED LASER PAINT STRIPPING (ALPS) UPDATE

Paul Lovoi *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Mar. 1993 12 p (For primary document see N94-10613 01-31)

Copyright Avail: CASI HC A03/MF A02

To date, the DoD has played a major role in funding a number of paint stripping programs. Some technologies have proven less effective than contemplated. Others are still in the validation phase. Paint stripping is one of the hottest issues being addressed by the finishing industry since the Environmental Protection Agency (EPA) has mandated that chemical stripping using methylene chloride/phenolic type strippers be stopped. The DoD and commercial aircraft companies are hard-pressed to find an alternative. Automated laser paint stripping has been identified as a technique for removing coatings from aircraft surfaces. International Technical Associates (InTA) was awarded a Navy contract for an automated laser paint stripping system (ALPS) that will remove paint from metallic and composite substrates. For the program, which will validate laser paint stripping, InTA will design, build, test, and install a system for fighter-sized aircraft at both the Norfolk and North Island (San Diego) Aviation Depots. AQUASTRIP (TM): AN INNOVATIVE PAINT REMOVAL TECHNOLOGY

J. Volkmar *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Mar. 1993 10 p (For primary document see N94-10613 01-31)

Copyright Avail: CASI HC A02/MF A02

Environmental, safety and health issues, forced operators to search for an alternative paint removal process. High pressure water jetting and new integrated paint and stripper systems are Lufthansa's answer to this challenge. AQUASTRIP complies with the specification requirements. In order to receive approval from airframe manufacturers and authorities the process has undergone an extensive research program since 1988. An operation window was established, to enable maximum of safety during operation on metal and composite surfaces. Even though AQUASTRIP is a hybrid process and requires technological investment, it is well on the way to prove its innovative, ecological and economical character in first large scale applications under realistic conditions. Its potential has already been reflected by patents and trademarks, which were registered in conjunction with the development of AQUASTRIP and the vital interest for cooperative work on the process development and other potential utilization. PAINT REMOVAL AND SURFACE CLEANING USING ICE PARTICLES
Terry Foster and S. Visaisouk (Ice Blast International Corp., Victoria, British Columbia.) *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Mar. 1993 10 p (For primary document see N94-10613 01-31)
Copyright Avail: CASI HC A02/MF A02

Research into the possibility of using ice particles as a blast medium was first initiated at Defence Research Establishment Pacific (DREP) in an effort to develop a more environmentally acceptable paint removal method. A paint removal process was also required that could be used in areas where normal grit blasting could not be used due to the possibility of the residual blasting grit contaminating machinery and other equipment. As a result of this research a commercial ice blasting system was developed by RETECH. This system is now being used to remove paint from substrates that cannot be easily blasted by conventional techniques and also to clean soiled or contaminated surfaces. The problems involved in the development of an ice blast system, and its components and their functions are described. Due to the complexity of paint removal using ice blasting, parameters such as air pressure, ice particle size and ice particle flow rate were studied and adjusted to suit the nature of the particular coating and substrate of interest. The mechanism of paint removal by ice particles has also been investigated. A theoretical model has been developed to explain the different paint removal mechanisms such as erosion by abrasion and erosion by fracture as they relate to ice blasting. Finally, the use of ice blasting to removal paint from a variety of substrates is presented as well as examples of surface cleaning and surface decontamination. Author

A review of the Wheat Starch Blasting technology is presented. Laboratory evaluations covering Almen Arc testing on bare 2024-T3 aluminum and magnesium, as well as crack detection on 7075-T6 bare aluminum, are discussed. Comparisons with Type V plastic media show lower residual stresses are achieved on aluminum and magnesium with wheat starch media. Dry blasting effects on the detection of cracks confirms better crack visibility with wheat starch media versus Type V or Type II plastic media. Testing of wheat starch media in several composite test programs, including fiberglass, Kevlar, and graphite-epoxy composites, showed no fiber damage. Process developments and production experience at the first U.S. aircraft stripping facility are also reviewed. Corporate and regional aircraft are being stripped in this three nozzle dry blast hanger. Author

In 1990 the International Air Transport Association (IATA) established a task force to stimulate the development of alternatives for chemical stripping of commercial aircraft. The IATA TaskForce Paintstripping objectives are: to identify the most promising, current alternatives for short term implementation; to prepare a document containing requirements for the development of alternatives; to stimulate the information exchange. After the September 1992 meeting the TaskForce will report back to IATA. The most tangible result of the TaskForce is the IATA Guidelines containing requirements for the qualification of stripping processes. Author (revised)

Implementation of a Total Quality Management (TQM) approach to engineering work required the development of a system of metrics which would serve as a meaningful management tool for evaluating effectiveness in accomplishing project objectives and in achieving improved customer satisfaction. A team effort was chartered with the goal of developing a system of engineering performance metrics which would measure customer satisfaction, quality, cost effectiveness, and timeliness. The approach to developing this system involved normal systems design phases including, conceptual design, detailed design, implementation, and integration. The lessons teamed from this effort will be explored in this paper. These lessons learned may provide a starting point for other large engineering organizations seeking to institute a performance measurement system accomplishing project objectives and in achieving improved customer satisfaction. To facilitate this effort, a team was chartered to assist in the development of the metrics system. This team, consisting of customers and Engineering staff members, was utilized to ensure that the needs and views of the customers were considered in the development of performance measurements. The development of a system of metrics is no different than the development of any type of system. It includes the steps of defining performance measurement requirements, measurement process conceptual design, performance measurement and reporting system detailed design, and system implementation and integration. DYNAMIC LOADING IN MANUFACTURING AND SERVICE: AUSTRALIA'S SHOCK TESTING CAPABILITY

P. Elischer and J. Howe 11 Feb. 1993 8 p
Avail: CASI HC A02/MF A01

Australia's involvement in shock testing to evaluate the structural response of Naval vessels and ships' equipment to transient dynamic loads began in late 1970. It commenced with gaining the necessary understanding of underwater blast phenomena and culminated in the successful shock testing of an Australian designed and constructed, glass reinforced plastic (GRP) minehunter. Since then we have maintained an active role in conducting full scale shock trials to evaluate the vulnerability of vessels and equipment supporting mine countermeasure operations. We also conduct smaller scale trials to support the submarine construction program and the various research tasks undertaken by DSTO. An overview of the shock trials conducted to date, together with a brief description of facilities available and considerations which needed to be addressed when conducting such tests in shallow water is presented. AN EFFICIENT MEDIUM ACCESS CONTROL STRATEGY FOR HIGH SPEED WDM MULTIACCESS NETWORKS
J. H. Laarhuis and A. M. J. Koonen 1992 41 p
(Memo-INF-92-74; TIOS-92/31; ETN-93-94322) Copyright Avail: CASI HC A03/MF A01

A medium access control strategy and a supporting physical layer design, which maximize the network throughput at given constraints on transceiver tunability, and which maintain the transparancy of the network, are proposed. The main requirements of multichannel networks are described. The wavelength demultiplexer (WDM) is one of the most attractive techniques to create multichannel networks. The physical layer architecture and the medium access control strategy are presented. Full interconnectivity, contention free access, and a high value of concurrency are achieved by dividing the network into disjunct subnetworks on a wave length basis and by reconfigurating these subnetworks on a time basis. Each subnetwork allows for simplified access to be implemented with fast tunable transceivers each accessing only a moderate number of wavelengths. A performance analysis shows that this concept is most efficient when applied to a high level broadband interconnection metropolitan area communications networks. ESA

MULTIPLE ANTENNA IMPLEMENTATION SYSTEM (MAntIS)
M. D. Carter, D. B. Batchelor, and E. F. Jaeger Jan. 1993 33 p
(Contract DE-AC05-84OR-21400)
(DE93-012515; ORNL/TM-12264) Avail: CASI HC A03/MF A01

The MAntIS code was developed as an aid to the design of radio frequency (RF) antennas for fusion applications. The code solves for the electromagnetic fields in three dimensions near the antenna structure with a realistic plasma load. Fourier analysis is used in the two dimensions that are tangential to the plasma surface and backwall. The third dimension is handled analytically in a vacuum region with a general impedance match at the plasma-vacuum interface. The impedance tensor is calculated for a slab plasma using the ORION-1D code with all three electric field components included and warm plasma corrections. The code permits the modeling of complicated antenna structures by superposing currents that flow on the surfaces of rectangular parallelepipeds. Specified current elements have feeders that continuously connect the current flowing from the ends of the strap to the feeders. The elements may have an arbitrary orientation with respect to the static magnetic field. Currents are permitted to vary along the length of the current strap and feeders. Parameters that describe this current variation can be adjusted to approximately satisfy boundary conditions on the current elements. The methods used in MAntIS and results for a primary loop antenna design are presented. DOE

FORMAL SPECIFICATION OF THE PLAIN UCN LAYER IN LOTOS
Jan Willem vanHeerde, Harro Kremer, and Hans Pasch Dec. 1992 167 p
(Memo-INF-92-83; TIOS-92/32; ETN-93-94324) Copyright Avail: CASI HC A08/MF A02

A new high speed local area network design that can be made to behave either like a token ring or a slotted ring, is presented. The name of the new proposal is Universal Channel Network (UCN). The UCN layer protocol and the formal specification of the UCN layer are summarized. While the token ring outperforms the slotted ring for long messages, a slotted ring performs significantly better for short messages. The factor that causes this difference is the number of tokens on the ring. In UCN, the number of tokens is adaptive, resulting in a network that can be made to behave like a token ring and a slotted ring or anything in between. The UCN performs optimally for any given message length. The reference model of UCN consists of the following layers: the medium layer, the basic slot layer, the UCN layer, and the UCN adaptation layer. The formal specification of UCN uses the specification language LOTOS. The service of the basic slot layer, which is used by the UCN layer, is described informally and formally. ESA

THE THEORY FOR, AND DEMONSTRATION OF, INFORMATION THEORY APPLIED TO RADAR TARGET IDENTIFICATION Ph.D. Thesis

S. D. Briles Jan. 1993 216 p
(Contract W-7405-eng-36)
(DE93-006393; LA-12480-T) Avail: CASI HC A10/MF A03 (US Sales Only)

The desire for a radar system to be able to identify a target under interrogation has motivated a long standing interest in determining the best possible performance of such radar target identification systems. With the advent of Ultra-Wideband radar, radar target identification became a more feasible task. Experimental performance has usually been presented without relationships to the difficulty of the problem, and design has primarily taken a trial and error approach. Tools are developed that can aid in the design of identification systems by applying information theory to the radar target identification problem. Specifically, by using the Bayes rate-distortion function, the minimum probability of error can be determined for the radar system in use and for the level of noise the system operates under. Performance changes, with such parameters as bandwidth, can be determined by using the Bayes rate-distortion function and calculations of mutual information for the various parameters. Proofs of the theoretical bases for using information theory for radar target identification are included. The continuous channel, inherent to the radar problem, is used in developing all proofs presented. An intuitive basis for using information theory is also presented from a signal detection theory background. Validity of the theory is demonstrated by using experimental radar target signatures of different bandwidths in Monte Carlo simulations. In addition, a method for computing mutual information is derived and performed on the experimental radar signatures to support the theory. DOE

INTERFERENCE PHOTOCATHODE Patent Application

John F. Seely, inventor (to Navy) and William R. Hunter, inventor (to Navy) 26 May 1992 26 p
(AD-D015770; US-Patent-Appl-SN-888083) Avail: CASI HC A03/MF A01

It is an object of the present invention to selectively reduce sensitivity to radiation of one wavelength while selectively enhancing sensitivity to radiation of a second wavelength, different from the first wavelength, in a photocathode. To achieve this and other objects made apparent hereinafter, the invention concerns a photocathode having a reflector for reflecting incident electromagnetic radiation, and an interference means for causing interference of electromagnetic radiation reflected from the reflector and incident electromagnetic radiation. The reflector and the interference means are adapted to cause the interference to result in an electromagnetic field zero at or near the surface of the interference means for incident electromagnetic radiation at a first selected wavelength, and to cause an electromagnetic field maximum at or near the surface for a second preselected electromagnetic wavelength. WIDE BAND 140 GHz TWTA Research Report, 1 Jan. - 30 Jun. 1992

16 Jul. 1992 26 p
(Contract DAAL01-92-C-0217)
Avail: CASI HC A03/MF A01

A single section low gain 140 GHz 200 watt travelling wave tube has been designed. The design uses the biperiodic ladder circuit of the 140 GHz extended interaction klystron amplifier developed on a previous Laboratory Command (LABCOM) contract. Circuit properties were obtained using X band models and the length of circuit needed for 20dB small signal gain was calculated as 0.9 inches (2.3 cm). Using X band models also, the required circuit to waveguide transitions were developed with voltage standing wave ratios of less than 1.3:1 within the operating band 137.5 to 142.5 GHz. The first experimental tube is expected to be tested in October 1992. Author (revised)

(DE93-013416; UCRL-JC-110202; CONF-9208109-82) Avail: CASI HC A01/MF A01

We have modeled gyrotron windows and gyrotron amplifier structures for TE modes in the 100-150 GHz range. Additionally, we have computed the reflection and transmission characteristics from the field data. Good agreement with frequency domain codes and analytic analysis was obtained for some simple geometries. We present results for realistic structures with lousy coatings. Finally, we describe implementation of microwave diagnostics. DOE

A NEW HMM LEARNING ALGORITHM FOR CONTINUOUS SPEECH RECOGNITION

Toru Imai and Akio Ando Mar. 1993 10 p
(NHK-Serial-413) Copyright Avail: Issuing Activity (NHK Science and Technical Research Laboratories, 1-10-11, Kinuta, Setagaya, Tokyo, 157 Japan)

Recently, hidden Markov models (HMMs) have been widely researched as an effective way of speech recognition. This paper describes a new HMM learning algorithm to obtain model parameters which appropriately describe training speech data. It is experimentally shown that the algorithm yields better recognition results than other training algorithms, and gives a good performance to a continuous speech recognition system for superimposing TV captions. OPTIMAL ROUTING OF IP PACKETS TO MULTI-HOMED SERVERS
K. L. Swartz Aug. 1992 9 p Presented at the 6th Usenix Systems Administration Conference on Large Installation System Administration, Long Beach, CA, 19-23 Oct. 1992
(Contract DE-AC03-76SF-00515)
(DE93-010949; SU-SLAC-PUB-5895; CONF-9210331-2) Avail: CASI HC A02/MF A01

Multi-homing, or direct attachment to multiple networks, offers both performance and availability benefits for important servers on busy networks. Exploiting these benefits to their fullest requires a modicum of routing knowledge in the clients. Careful policy control must also be reflected in the routing used within the network to make best use of specialized and often scarce resources. While relatively straightforward in theory, this problem becomes much more difficult to solve in a real network containing often intractable implementations from a variety of vendors. This paper presents an analysis of the problem and proposes a useful solution for a typical campus network. Application of this solution at the Stanford Linear Accelerator Center is studied and the problems and pitfalls encountered are discussed, as are the workarounds used to make the system work in the real world. DILUTE: A CODE FOR STUDYING BEAM EVOLUTION UNDER RF NOISE
H. J. Shih (Superconducting Super Collider Lab., Dallas, TX.), J. Ellison (New Mexico Univ., Albuquerque.), and W. Schiesser (Lehigh Univ., Bethlehem, PA.) Apr. 1993 9 p Presented at the Computational Accelerator Physics Conference (CAP93), Pleasanton, CA, 22-26 Feb. 1993
(Contract DE-AC35-89ER-40486)
(DE93-011605; SSCL-Preprint-220; CONF-930269-12) Avail: CASI HC A02/MF A01

Longitudinal beam dynamics under RF noise have been modeled using a diffusion-inaction PDE. If the primary interest is the evolution of the beam in action, it is much simpler to integrate the model PDE than to undertake tracking simulations. Here we describe the code that we developed to solve the model PDE using the numerical Method of Lines. Features of the code include the following: (1) computation of the distribution in action for the initial beam from a Gaussian or user-supplied distribution in longitudinal phase space; (2) computation of the diffusion coefficient for white noise or from a user-supplied spectral density for non-white noise; (3) discretization of the model PDE using finite-difference or Galerkin finite-element approximations with a uniform or non-uniform grid; and (4) integration of the system of ODE's in time by the solver RKF45 or a user-supplied ODE solver. MEASUREMENT OF DISPLAY TRANSFER CHARACTERISTICS USING TEST PICTURES
A. Roberts 1992 11 p
(BBC-RD-1992/13) Copyright Avail: BBC, Kingswood Warren, Tadworth, Surrey, England

There are three basic parameters which define the transfer characteristic of monitors: contrast, flare, and gamma. Each of these can be measured, with varying degrees of accuracy, by a variety of methods. This Report attempts to clarify the definitions of the terms and to specify methods of measurement which give unique and repeatable results. Test pictures are described which permit measurements to be made precisely and rapidly. The test picture for gamma measurement can be used both subjectively and objectively, and gives results which compare well with those produced by the classical method of making point-by-point measurement of the transfer function. The test pictures for flare and contrast give results which are specific to those test pictures only, these results can be used only for making relative assessments of monitors and cannot be used to make accurate predictions of the color performance of a monitor. Digital Audio Broadcasting (DAB) is being considered as a future method of transmitting radio programs to the public. Some of the advantages of DAB over conventional Frequency Modulation (FM) include its resistance to multipath and its ruggedness in the presence of interference. Because of these qualities it is ideally suited for reception by mobile and portable receivers. It is proposed that a DAB service will be planned to be effective for use by fixed, portable, and mobile receivers. But many problems have to be overcome, to allow accurate planning of suitable transmitter sites and powers, if the desired coverage is to be obtained economically. This Report gives the results of one aspect of this work, namely the signal level received within a building compared to the level received outside. This is generally termed building penetration loss. Several different frequency bands are being considered for DAB transmission in the UK. The work reported concentrates on one of the proposed bands: Band III. The two broad aims of the work were: (1) by measuring the field strength both inside and outside buildings, determine a Building Penetration Loss figure; and (2) using first generation prototype Coded Orthogonal Frequency Division Modulation (COFDM) equipment, find the relationship between field strength and some particular values of Bit Error Ratio (BER). A mean building penetration loss of approximately 8 dB was measured for the whole of the ground floor of brick-built houses. Using first generation prototype DAB transmitting and receiving equipment, in the absence of interference, a field strength of the order of 39 dB (microV/m) will provide the receiver with an adequate signal. Further work is essential to quantify the lower limit of felt strength in which a trial specification receiver will work. There is a potential saving of up to 5 dB on transmitter powers, depending on the particular levels of ambient man-made noise. Author (revised)

Nonlinear dynamics of auto vibration processes in a distributed electron beam - backward electromagnetic wave system is described. It was shown that depending on the correlation between the wave complification parameter and initial electron beam energy, the considered system may demonstrate different mechanisms of transition to autostochastic vibrations. In particular, it was established that such a transition may be realized through the sequence of period doubling bifurcations. The efficiency of irregular auto vibration excitations is determined. The problem of tensor Green function formulation for electric vector potential G(sub e)(r-vector,r'-vector) is solved as a problem of tensor spheric wave diffraction on inner surface of a round waveguide. It is shown that G(sub e)(r-vector,r'-vector) is a superposition of tensor Green-function of free space and a regular Green function of round waveguide G(sub e)(sup (0))(r-vector,r'-vector) being a solution of homogeneous Helmholz equation which satisfy unhomogeneous boundary conditions on waveguide surface. The obtained results may be applied in design of UHF installations and accelerating technique in which charged round waveguides are used. DOE

LINEAR ANTENNA OF AN ARBITRARY ORIENTATION AND POSITION IN CYLINDRIC SCREEN [LINEJNAYA ANTENNA PROIZVOL'NOJ ORIENTASII I POLOZHENIYA V TSILINDRICHESKOM EHKRANE]

S. D. Prijmenko, V. G. Papkovich, and N. A. Khizhnyak 1991 9 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621353; KFTI-91-29) Avail: CASI HC A02 (US Sales Only)

An equation of the linear antenna in cylindric screen is formulated. Using the averaging method a solution of this equation for the antenna of arbitrary orientation which does not contact the screen walls or contacts them in one or two ends is received. The obtained asymptotic expression for stream permits to describe in a single manner the case of resonance and non-resonance scattering. These results may be applied in design of UHF and accelerating installations using cylindric screens charged with linear vibrators. DOE

On the basis of the Hausdorf dimension concept, a dynamic system complexity is defined as a minimal dimension of the phase volume in which its attractor may be included. A procedure of such a dimension determination according to timely realization of one variable is proposed. The dimensions of some experimental realizations and that of one mathematical model are found. DOE

ASYMPTOTIC EXPRESSIONS FOR REGULAR GREEN FUNCTIONS OF A ROUND CYLINDRICAL SCREEN [ASIMPTOTICHESKIE VYRAZHENIYA FUNKTSIJ GRINA KRUGOVOGO TSILINDRICHESKOGO EHKRANA]

S. D. Prijmenko and N. A. Khizhnyak 1992 16 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-621356; KFTI-92-4) Avail: CASI HC A03 (US Sales Only)

Asymptotic expressions of tensor regular Green functions for electric vector potential G(sub e)(sup (o) and magnetic vector potential G(sub mu)(sup o) of a round cylindric screen are obtained. In low-frequency approximation G(sub e)(sup o) and G(sub mu)(sup o) for a synphase linear current source are described by Green function of the secondary source with an addition in the form of finite series. In high-frequency approximation: at internal excitation by a synphase linear current source asymptotic correlations are represented by an infinite sum of secondary current source Green functions; at external excitation G(sub mu)(sup o) for a synphase linear current source and G(sub e)(sup o) for a point current source have a form of closed expressions. The obtained results may be applied in design of UHF, antenna and accelerating installations using charged cylindric screen. DOE

PROPAGATION EFFECTS IN SPACE VLBI

Leonid I. Gurvits, ed. (Academy of Sciences, USSR, Moscow.) Arecibo Ionospheric Observatory 1993 109 p Workshop held in Leningrad, Russia, 28-30 May 1990 Sponsored by NSF; Academy of Sciences (USSR); and Special Astrophysical Observatory
Copyright Avail: Issuing Activity

Very Long Baseline Interferometry (VLBI) leads all other kinds of astronomical techniques in achieving the highest angular resolution. The main purpose of the workshop was to discuss some possible complications of VLBI experiments with baselines longer than the Earth's diameter due to propagation phenomena in the various media. Papers presented at the workshop are included. For individual titles, see N94-11061 through N94-11071.

RADIOWAVES PROPAGATION THROUGH INHOMOGENEOUS INTERSTELLAR PLASMA

V. I. Shishov *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 1-12 (For primary document see N94-11060 01-32)
Avail: Issuing Activity

Data on measurements of the effects of scattering, short-period and long-period scintillation of pulsars and quasars which are caused by modulation of radiowaves propagating through interstellar plasmas with turbulent inhomogeneities are analyzed. Arguments are stated in favor of piecewise power form of spatial spectrum of electron density with sharp decrease of level on scale of 1 = 10(exp 13)cm. The estimation of the angle of scattering, specific temporal and frequency scales of scintillations for an extragalactic source, located in the vicinity of galaxy pole, is presented. THE INFLUENCE OF THE PROPAGATION MEDIUM ON THE SENSITIVITY AND RESOLUTION OF METER WAVELENGTH APERTURE SYNTHESIS SYSTEMS

A. V. Kukushkin *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 13-22 (For primary document see N94-11060 01-32)
Avail: Issuing Activity

Among the effects restricting the sensitivity and resolution of radio interferometers stands out scattering in the medium where the waves propagate, i.e., the ionosphere, the interplanetary or interstellar plasma. In a majority of papers dedicated to the problem, the weak scattering approximation is considered and proves sufficient owing to the frequency range employed. The currently existing aperture synthesis systems and radio interferometers operate, for the most part, at the centimeter wavelengths, in which band scattering effects are reasonably weak both in the interplanetary plasma (IPM) and the ionosphere. Representative scales of wave front pertubations owing to the interstellar plasma exceed the maximum size of the synthesized apertures of Earth based systems. A more detailed theoretical analysis of the scattering effects with an application to the characteristics of the aperture synthesis systems is suggested. Author (revised)

INTERSTELLAR SCATTERING AND THE SELECTION OF EXTRAGALACTIC RADIOSOURCES WITH HIGHLY COMPACT COMPONENTS

Brian Dennison, R. L. Fiedler (Naval Research Lab., Washington, DC.), K. J. Johnston (Naval Research Lab., Washington, DC.), and R. L. Simon (Naval Research Lab., Washington, DC.) *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 23-32 (For primary document see N94-11060 01-32)
Avail: Issuing Activity

Interstellar scattering of radiowaves imposes strong constraints upon the resolution of fine scale intrinsic structure in compact sources. Depending upon frequency and galactic latitude, some high resolution observations will probably be dominated by scattering. Nevertheless, orbiting VLBI will provide opportunities to observe directly refractive distortions, especially those connected with extreme scattering events. An additional consequence of the similarity of the putative refractive angular scale and RADIOASTRON resolution is that observations of refractive scintillation provide rudimentary information on the compact flux on these scales. INTRADAY VARIABILITY AND THE COMPACTNESS OF EXTRAGALACTIC RADIO SOURCES

A. Witzel and A. Quirrenbach *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 33-44 (For primary document see N94-11060 01-32)

Avail: Issuing Activity

Recent advances in the technology of radio interferometry have led to a substantial improvement of the resolution achievable in observations of extragalactic objects. By proceeding from cm wavelengths into the mm regime and leaving the ground to form earth-satellite baselines, submilliarcsecond resolution has become feasible. Since both mm-VLBI and space projects are maturing from 'first fringes' to scientifically productive techniques, the quest for ultra-compact sources, which are potential candidates for high-resolution studies, has become an increasingly important issue. Historically, it was the flux density variability of extragalactic compact sources on the timescale of weeks to several months that triggered the development of VLBI in the late sixties: The existence of compact structures inferred from the variations on the basis of light travel time arguments (and more indirectly from the shape of the synchrotron spectra) gave the scientific justification to build instruments with a resolving power in the milliarcsecond range. The successful direct observations of the small-scale structures of strong sources, the detection of apparent superluminal motion, and later the detailed images obtained by hybrid mapping procedures led to an excellent confirmation of the predictions and to numerous refinements of the earlier theories on compact sources. Specifically, it could be shown that flux density variations in the cm and mm ranges are frequently accompanied by structural variations, thus showing that the former are really intrinsic to the sources. However, the apparent consistency of the picture of compact radio sources was challenged by the extremely high brightness temperatures derived from low frequency variability. Therefore, Shapirovskaya's suggestion that interstellar scintillation should play a significant role at least in some sources was widely accepted; and separating propagation effects from intrinsic variability became an important and difficult issue in the analyses of light curves, except at very high frequencies. The importance of scattering in the interstellar medium even at cm wavelengths was reinforced by the detection of unusual 'high amplification events' at 3.6 and 11 cm. Also small-amplitude flickering on the timescale of a few days can be readily explained by refractive interstellar scintillation. Flux density variability on time scales of a day or even less in extragalactic radio sources had not been convincingly demonstrated before intraday variability was found in several high-declination flat spectrum sources. Although the physical origin of these variations has not yet been indisputably identified, a very high degree of compactness can be inferred for short-timescale variables, making them prime targets for ultra-high resolution studies. Clearly, there is also an important impact of short time scale variations on interferometry by its influence on aperture synthesis. The present status of our observations on intraday variability is reported and some ideas on their interpretation are discussed. Author (revised)

INTERSTELLAR SCATTERING AND THE PULSAR STUDIES WITH SPACE VLBI c93

James M. Cordes *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 45-56 Sponsored by National Astronomy and Ionosphere Center (For primary document see N94-11060 01-32)

Avail: Issuing Activity

Observable interstellar scattering phenomena (angular broadening, temporal broadening, diffractive scintillations, angle of arrival variations, and time of arrival variations) are used to show that: (1) the wave number spectrum of electron density fluctuations is Kolmogorov in form over at least five orders of magnitude in wave number; there may be an implied inner scale of approximately few x 10(exp 7) cm. All observables yield an implied scattering measure (SM, the line of sight integral of the spectral coefficient C(sup 2)(sub n) that varies by at least 5 orders of magnitude between lines of sight; and (3) the Galactic distribution of scattering material, as inferred from analysis of SM, displays both large scale systematic structure and localized enhancements. A fit of an axisymmetric model shows two components with scale heights of 0.05 and 0.5 kpc and galactrocentric radial scales approximately greater than 20 kpc and 7 kpc. The small scale height component is stronger than the other by a factor approximately 2000. From the model fit, predictions for angular broadening as a function of galactic coordinates l,b are given for extragalactic sources at the four frequencies of interest to RADIOASTRON. Several projects are suggested for RADIOASTRON that will enhance our understanding of the galactic turbulence that causes scattering and that aim at resolving pulsar magnetospheres. These include: angular broadening of nearby pulsars; angular broadening of extra galactic sources for the absolute value of b is approximately less than 1 deg toward the galactic anticenter; and interferometry of pulsars using very large baselines, b is approximately 0.1-1 AU. The first two projects require a one day orbit, the last an interplanetary orbit. Author (revised)

VLBI AND THE DETECTION OF INTERSTELLAR MAGNETOHYDRODYNAMIC WAVES c75

Steven R. Spangler *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 57-67 (For primary document see N94-11060 01-32)

Avail: Issuing Activity

The capability of Very Long Baseline Interferometry (VLBI) for measuring plasma turbulence in the interstellar medium on interestingly small scales is discussed. These scales are sufficiently small that the irregularities should be part of plasma waves which partake in processes such as resonant interaction with cosmic rays. VLBI results to date show that intense scattering can occur in regions of small spatial extent. Specific regions such as supernova remnants and interstellar bubbles, which are good candidates for generation of plasma density fluctuations are examined. The capacity of Radioastron to further this area of research is discussed. With longer baselines, Radioastron will be capable of detecting regions with smaller scattering measure than can presently be detected. This might produce important new observational results in plasma astrophysics.

GENERALIZATION OF DYSON CRITERION FOR THE AMPLITUDE-PHASE FLUCTUATIONS CASE AND FOR THE SYSTEM OF INTERFEROMETERS

V. I. Tatarskii *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 68-78 (For primary document see N94-11060 01-32)

Avail: Issuing Activity

It is well known that due to the medium parameters fluctuations some restrictions on the resolution of the Very Long Baseline Interferometry (VLBI) arise. Some special methods to compensate this effect are developed. The adaptive systems and processing of signals are the examples of such methods. In fact both are two different ways to realize the same ideas. For the adaptive optical systems, some different criteria C(sup i) were suggested, that condition C(sub i) = max, corresponds to elimination of phase fluctuations on the input aperture. Some of these criteria are based on the difference in the time scales and spatial behavior of fluctuations which are caused by source properties and by medium properties. For example, if the source fluctuations have a very short correlation time and spatial scale in comparison with the corresponding values of medium fluctuations, it is possible to distinguish them using this difference. To use such methods it is not necessary to have the reference point source. Thus, such methods are rather universal. One such method is considered. The model of source, then the interferometrical measurements in the homogeneous medium is analyzed. The well known Dyson criterion for the phase fluctuations is derived. It is shown, that this criterion is valid only for the small enough angle sizes of source. Two generalizations are made: it is shown how it is possible to use the Dyson criterion in the presence of intensity fluctuations (including the case of strong and saturate fluctuations) and how to formulate it if the field is measured only for the discrete system of observation points (telescopes). The corresponding algorithm of the signal processing is formulated. The influence of the

additive noise on the Dyson criterion is analyzed. It is shown also that Dyson criterion is useless, if the angle size of source is not small enough.

Avail: Issuing Activity

It is well known that the angular resolution of a telescope is limited by diffraction on the aperture and the solution of an interferometer is defined by the length of its base. In fact, due to atmospheric turbulence (if long-exposure images are recorded), the resolution of large telescopes and long base interferometers is determined not so much by diffraction as by medium-induced wave front perturbations. But in the case of short exposure when image averaging does not take place, one can observe details with diffraction limited resolution. This property of short exposure images was used by Labeyrie as the basis for the speckle interferometric method. Nowadays there are many modifications of this method, allowing restoration of an image with diffraction-limited resolution by computer processing of short-exposure images and interferometric signals. It seems obvious that turbulence is a disturbing noise factor. But under certain conditions it may produce a positive effect; however paradoxical it sounds, it may lead to an increase in the resolution beyond the diffraction limit. Theoretical and experimental results concerning this phenomenon are described elsewhere. A theoretical description of this effect for interferometric imaging is given. Author (revised)

TROPOSPHERIC AND IONOSPHERIC EFFECTS ON DIFFERENTIAL ASTROMETRY WITH A GROUND-SPACE BASED VLBI ARRAY
Norbert Bartel *In* National Astronomy and Ionosphere Center, Propagation Effects in Space VLBI 1993 p 90-101 (For primary document see N94-11060 01-32)
(Grant NSF AST-89-02087)
Avail: Issuing Activity

The effects of the troposphere and the ionosphere on the interferometric delay in differential ground-based astrometric VLBI observations are analytically and empirically investigated and compared with other effects influencing the accuracy of such observations. The results from this investigation are then used to estimate the tropospheric and ionospheric effects in ground space based VLBI observations such as those anticipated with RADIOASTRON, VSOP, and IVS. It is found that tropospheric effects can most likely be corrected easily with standard methods and with sufficient accuracy not to dominate the error budget of position determinations. Ionospheric effects at frequencies approximately greater than 1.7 GHz are also not likely to dominate such error budget if the standard errors of the components of the baseline vectors are approximately greater than 10 m. In contrast, if the components of the ground-space baseline vectors have standard errors approximately less than 1 m, ionospheric effects at frequencies are approximately less than 2 GHz could still be a significant contribution to such an error budget, even if more elaborate correction methods are applied. RADIATION AND SCATTERING BY CAVITY-BACKED ANTENNAS ON A CIRCULAR CYLINDER Semiannual Report, Feb. - Aug. 1993
Leo C. Kempel and John L. Volakis Jul. 1993 69 p
(Grant NAG1-1478)
(NASA-CR-193409; NAS 1.26:193409; UM-030601-1-T) Avail: CASI HC A04/MF A01

Conformal arrays are popular antennas for aircraft and missile platforms due to their inherent low weight and drag properties. However, to date there has been a dearth of rigorous analytical or numerical solutions to aid the designer. In fact, it has been common practice to use limited measurements and planar approximations in designing such non-planar antennas. The finite element-boundary integral method is extended to scattering and radiation by cavity-backed structures in an infinite, metallic cylinder. In particular, the formulation specifics such as weight functions, dyadic Green's function, implementation details, and particular difficulties inherent to cylindrical structures are discussed. Special care is taken to ensure that the resulting computer program has low memory demand and minimal computational requirements. Both scattering and radiation parameters are computed and validated as much as possible.

DESIGN OF A MATCHING NETWORK FOR DIPOLE ANTENNAS M.S. Thesis
Jennifer Park Mar. 1993 55 p
(AD-A265115) Avail: CASI HC A04/MF A01

The input impedance of an antenna is highly dependent on the frequency range in which it operates. For an electrically small antenna to operate in a broad frequency range, the antenna must be properly matched. This thesis presents the design of a matching network for a 1-meter monopole antenna, operating over 30-90 MHz using the real frequency method (RFM). It outlines the mathematical steps needed to determine the equalizer function, which ultimately leads to the circuit design. The goal of the RFM, given the real frequency data, is to optimize the Transducer Power Gain (TPG) and minimize the reflection coefficient or power lost due to the impedance mismatch. Complete design including network realization is given. However, no experimental results are presented. DTIC

TELESCIENCE CAPABILITY FOR THE SONDRE STROMFJORD, GREENLAND, INCOHERENT-SCATTER RADAR FACILITY Final Report, 15 Aug. 1991 - 14 Jan. 1993
Yadunath B. Zambre Jan. 1993 13 p
(Grant NAG5-1728; SRI Proj. 2724)
(NASA-CR-193683; NAS 1.26:193683) Avail: CASI HC A03/MF A01

SRI International (SRI) operates an upper-atmospheric research facility in Sondre Stromfjord (Sondrestrom), Greenland. In the past, the facility's remote location and limited logistical support imposed constraints on the research that could be carried out at the site. Campaigns involving multiple instruments were often constrained due to limited space, and experiments requiring coordination with other geographically separated facilities, though possible, were difficult. To provide greater access to the facility, an electronic connection between Sondrestrom and the mainland U.S.A. was established, providing access to the National Science Internet. SRI developed telescience software that sends data from the incoherent scatter radar at the Sondrestrom facility to SRI's offices in Menlo Park, California. This software uses the transmission control protocol (TCP/IP) to transmit the data in near real time between the two locations and the X window system to generate displays of the data in Menlo Park. This is in contrast to using the X window system to display data remotely across a wide-area network. Using CP to transport data over the long distance network has resulted in significantly improved network throughput and latency. While currently used to transport radar data, the telescience software is designed and intended for simultaneous use with other instruments at Sondrestrom and other facilities. Work incorporating additional instruments is currently in progress. Author (revised)

(Grant NAG3-1368)
(NASA-CR-193310; NAS 1.26:193310) Avail: CASI HC A03/MF A01

In Feb. 1993, the Solar Power Satellite (SPS) Working Group from ISAS, Japan will launch a sounding rocket into low earth orbit to perform two activities: collect scientific information on the high power microwave-ionosphere interaction, and demonstrate microwave power transmission in space at 2.45 GHz. The SPS Working Group announced an open invitation to international agencies willing to collaborate with the Microwave Energy Transmission in Space (METS) experiment in a number of categories. Under the sponsorship of the NASA's Lewis Research Center, the Center for Space Power located at Texas A&M University joined the experiment by producing a microwave rectifying receiving antenna (rectenna). The rectenna is a special type of receiving antenna with unique properties and characteristics. The rectenna's main purpose is to efficiently convert microwave power into DC power. The rectenna is an advanced component in microwave power beaming technology developed for 2.45 GHz. The state-of-the-art rectenna for this frequency consists of dipole antennas, filter circuits, and transmission lines etched on a thin layer of Kapton film. The format of the thin film rectenna is ideally suited for space applications. Thin film rectennas have a low specific mass of approximately 1 kg/kW. The main component of the rectenna is the rectifying diode. High conversion efficiencies (90 percent) in microwave to DC power are capable with special Schottky barrier diodes correctly located in the rectenna circuitry. The theory of operation of the 2.45 GHz rectenna is explained. Experimental test results on the METS rectenna are presented. The packaging of the rectenna is also discussed to meet space qualifications. Author (revised)

(DE93-009517; UCRL-JC-110117; CONF-9208127-7) Avail: CASI HC A01/MF A01

In propagating significant distances in the ionosphere, a short microwave pulse will undergo strong dispersion from the ambient electrons it encounters. The pulse will be extended in time with dramatic reductions in peak amplitude and power. This undesirable dispersive reduction may be counteracted by transmission of a frequency-chirped pulse. In principle, with the proper initial pulse and a sufficient knowledge of the ionospheric electron density distribution, compressed pulses are possible at many points in the ionosphere. We use two computational methods to examine ionospheric compression of plane-wave pulses with several waveforms. DOE

ON THE COUPLING OF ELECTROMAGNETIC RADIATION INTO CAVITIES

T. J. T. Kwan Mar. 1993 13 p
(Contract W-7405-eng-36)
(DE93-011406; LA-12493-MS) Avail: CASI HC A03/MF A01

We present a comprehensive report of time-resolved reflectivity and transmission measurements of the superconducting system Pr(x)Y(1-x)Ba2Cu3O(7-delta). For a fixed photon energy (1.98 eV), varying the Pr content permits optical probing of energy states both above and below the Fermi level where a superconducting gap is expected to occur. We find qualitatively different behavior in the sign, magnitude, and temporal responses as a function of Pr fraction. Our results indicate that a simple two-fluid model interpretation cannot account for the observed response and that the intrinsic band structure of Pr(x)Y(1-x)Ba2Cu3O(7-delta) plays a significant role in the dynamics of these systems. DOE

PO/PTD DIFFRACTION SYNTHESIS OF ARRAY-FED REFLECTOR ANTENNAS FOR SATELLITE AND RADAR APPLICATIONS Ph.D. Thesis

Dah-Weih Duan 1992 252 p
Avail: Univ. Microfilms Order No. DA9310918

Reflector antennas find wide applications in satellite communications, direct broadcast satellite (DBS) communications, radar systems, radio astronomy, and deep space telemetry. The ever increasingly stringent requirements on the antenna performance have demanded the development of sophisticated synthesis/analysis techniques. For this purpose, a diffraction synthesis methodology, which combines the optimization techniques and the diffraction analysis techniques of Physical Optics (PO) and Physical Theory of Diffraction (PTD,) is developed. This methodology is used to solve the problems of synthesizing single and dual-reflector antennas with an arbitrarily configured array feed. In the analysis, the PTD technique is reformulated using a general approach, and a singularity analysis is performed. The inaccuracy of the PO field in the far-angular regions and cross-polarized field predictions are effectively corrected by the PTD fringe field. In the synthesis, reflector shaping is achieved by adjusting the coefficients of a Jacobi-Fourier global surface expansion, which yields reflectors that are characterized by smooth surfaces, well defined boundaries, and continuous surface derivatives. The edge diffraction and the near-field effects are automatically taken into account in the synthesis. The reflector aperture is allowed to vary from an ellipse (circle) to a rectangle (square) using the superquadric function, and the array feed may consist of point sources or aperture type of feeds (horns). Alternative reflector antenna configurations and concepts developed using the PO/PTD diffraction synthesis/analysis technique are demonstrated through example applications such as high gain dual-reflector antennas, reflector surface distortion compensation, High Power Microwave (HPM) antenna systems, and contoured-beam satellite antennas. Dissert. Abstr.

BOUNDARY INTEGRAL SOLUTION TO THE ELECTROMAGNETIC SCATTERING FROM COATED SURFACES CONTAINING EDGES, GAPS, AND PERIODIC GRATINGS Ph.D. Thesis

John Thomas Moore 1992 103 p
Avail: Univ. Microfilms Order No. DA9309235

A boundary integral approach is used to investigate the electromagnetic scattering from three types of coated structures: the isolated gap in a coating, the semi-infinite coated edge, and the coated periodic grating. For the gap in the coating, the numerical implementation of the solution is facilitated by removing the specular fields and the surface wave contributions from the boundary integral equation. Consequently the discretization domain of the infinite structure can be reduced to a localized region near the gap.

Numerical diffraction coefficients and surface wave launch coefficients are extracted from the scattered field. The results of this approach are validated against a spectral integral solution to the gap, and excellent agreement is observed. For the semi-infinite edge, an exact boundary integral formulation is used without resorting to the impedance boundary condition approximation. As is done for the coated gap, numerical diffraction coefficients and surface wave launch coefficients are extracted from the scattered field. Solutions to several finite sized coated strips are constructed using the numerical diffraction coefficients and are shown to be valid for a variety of strip configurations. The solution to a coated strip with a gap is constructed one mechanism at a time via a high frequency ray framework. This numerical 'building block' approach provides a clear physical picture of the complex scattering mechanisms in coated structures. Finally, a boundary integral formulation is presented for computing the scattering from material coated periodic gratings under oblique incidence. Periodic boundary conditions and expansion of the fields in terms of Floquet harmonics allow the boundary integral formulation to treat just a single period of the infinite grating. Numerical results for etched conducting gratings designed for use at infrared wavelengths are presented and shown to be in good agreement with a series of measurements. Results for a number of dielectric gratings for both normal and oblique incidence also agree well with other published data. The conductor-backed coated grating is also studied, and it is shown that the groove profile can be used to significantly alter the absorbing characteristics for lossy material coatings. Dissert. Abstr.

DISTURBANCE IMPACT ASSESSMENT SYSTEM (DIAS), VERSION 2.0. SYSTEM DESIGN DOCUMENT Final Report, 1990 - 1992
R. B. Rose and D. R. Lambert Feb. 1993 260 p
(AD-A265251; NCCOSC/RDT/E-TD-2452) Avail: CASI HC A12/MF A03

This technical document, actually a system design document or functional description document, covers the Disturbance Impact Assessment System (DIAS). This system is a computer software package designed to assess the effects of solar flares on HF radio communications. The document describes its software functions and their interrelationships. Specifically, the document provides background information on the effects of high levels of solar activity on high-latitude HF missions, outlines the architecture of DIAS, and defines the product that DIAS provides to the user. FEATURE ASSOCIATION WITHOUT A MOTION ESTIMATE
R. L. Ricks Apr. 1993 3 p
(AD-A265162) Avail: CASI HC A01/MF A01

The problem of associating the features of a moving object in sequential images without estimates of object motion or structure (relative position of features) is addressed. A method is presented and analyzed for associating features even if some of the features are occluded (not visible in one or more of the images of interest). The method models the object as a rigid set of point reflectors each with independent reflectivity that is correlated from image to image. Object motion is modeled as a circular trajectory in a known plane. It requires measurements of position plus Doppler. Such measurements are available from monopulse radar and some sonar and laser imaging systems. The method assumes all possible associations and minimizes the least trimmed squares (LTS) of error residuals to remove erroneous associations. Byproducts of the minimization include estimates of object motion and feature structure. DTIC

DESIGN OF A CONTINUOUS RESISTIVELY LOADED MONOPOLE ANTENNA Interim Report, 1 Jan. - 1 May 1993
Darwish A. Mohamed and Ramakrishna Janaswamy 1 May 1993 34 p
(AD-A265852; NPSEC-93-011) Avail: CASI HC A03/MF A01

Hallen's integral equation with continuous resistive loading is used to design a broadband monopole antenna. The resistive profile is different from that of the well known Wu-King profile and results in a higher efficiency compared to the latter. An optimization function for determining the optimal continuous resistive load of the monopole antenna in order to satisfy the broadband property is constructed. The simplex method is used to perform the optimization. The integral equation is solved by the moment method to determine the current distribution, the efficiency, and the radiation pattern of the monopole. DTIC

(AD-A265673; AFOSR-93-0391TR) Avail: CASI HC A02/MF A01

This first topic deals with a new procedure to carry out nonlinear transformations commonly encountered in practical surveillance systems. The procedure eliminates the bias and provides a correct (rather than optimistic) covariance matrix. The topics covered in sections 2, 5 and 6 deal with discrete optimization (assignment) techniques applied to various multisensor-multitarget problems including ballistic missile track initiation from a passive orbiting sensor. Section 3 presents some new efficient factorization algorithms that improve the numerical accuracy for several advanced state estimation filters used in practice. Section 4 deals with evaluation of performability measure of complex manufacturing systems. DTIC

ISAR MOTION COMPENSATION USING THE BURST DERIVATIVE MEASURE AS A FOCAL QUALITY INDICATOR Professional Paper
Richard P. Bocker and Scott A. Jones Apr. 1993 2 p Sponsored by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265647) Avail: CASI HC A01

Inverse synthetic aperture radar (ISAR) is an imaging technique that shows great promise in classifying airborne targets in realtime, under all weather conditions. The success of classifying targets using ISAR is predicated upon forming highly focused radar images of these targets. Efforts to develop highly focused imaging computer software have been challenging, mainly because the imaging depends on and is affected by the motion of the target. Computationally intensive motion compensation algorithms have been developed to remove the unwanted degrading effects of target motion. Those particular motion compensation algorithms which require the use of a space-domain focal quality indicator, e.g., entropy, to determine image sharpness as processing proceeds pay a severe computational penalty due to the large number of two-dimensional fast Fourier transforms (2D-FFT's) which must be computed. This is due to the fact that the actual processing of ISAR data is primarily done in the spatial frequency domain and not in the space-domain where the final ISAR image is displayed. If a focal quality indicator could be developed to measure image sharpness in the spatial frequency domain, then the computational burden introduced by the numerous 2D-FFT's could be greatly relaxed. This paper describes the use of a new focal quality indicator called the burst derivative measure for determining ISAR image sharpness in the spatial frequency domain. Tests have been performed on simulated as well as actual ISAR data using both the burst derivative measure and the entropy measure. DTIC

(Grant NAGw-1278)
(NASA-CR-194030; NAS 1.26:194030; RSL-TR-7970-2) Avail: CASI HC A13/MF A03

The University of Kansas and the University of Washington conducted a series of experiments during July and August of 1989, and July and August of 1990, to study the effects of various geophysical parameters on radar backscatter. The experiments were conducted from a platform in Lake Washington. Measurements of backscattered power and radar range were made by the University of Kansas, and environmental data such as wind speed, wind direction, and air and water temperature were measured by the University of Washington. Results of preliminary data processing are described. Radar data were acquired using two radars, one that operated at C and X bands and another at Ka band. Measurements were made at W and HH antenna polarizations, at different angles of incidence and under various wind conditions. Plots of backscattered power, normalized radar cross section, and wave height, and the Modulation Transfer Functions of selected data are presented. Author (revised)

The fabrication and first performance tests of a prototype superconducting radio-frequency quadrupole resonator (SRFQ) are described. The SRFQ operates at 57 MHz and is optimized for a particle velocity of beta = 0.033. It is constructed of copper electroplated with a lead-tin alloy. An accelerating field gradient of 1.25 MV/m was achieved with about 7 watts of helium dissipation. This corresponds to an energy gain of 700 keV per unit charge over the 56 cm overall diameter of the resonator. DOE

The Aerocapacitor is an electrochemical double-layer energy-storage device that utilizes carbon aerogels as electrodes. In this paper, the effect of 1M electrolyte composition on the Aerocapacitor's average-integral (AIC) and differential capacitance is investigated. The AIC values range from 7.2 to 22.5 F/cc for the electrode formulation used in this study. Typically, the AIC increase by a factor of two, and the differential capacitance by a factor of four, between 0 and 1.2 V. DOE

It is therefore an object of the present invention to provide a field emitter device which substantially eliminates the need for the use of high spatial resolution lithography in its fabrication. It is another object of the present invention to provide a field emitter device having inherent advantages over previous electron sources, including higher emission currents, lower power requirements, less expensive fabrication costs and ease of integration with other circuitry. It is a further object of the present invention to fabricate gated and ungated thin-film edge field emitter devices wherein the spacing between the elements is small enough to enable low voltage operation. It is a further object of the present invention to fabricate FEA's over a large area in a manner which is inexpensive, yet results in an equal or greater degree of precision and reproducibility when compared with other prior art processes. (NASA-CR-185273; E-7929; NAS 1.26:185273) Avail: CASI HC A04/MF A01

Permanent magnet excited linear alternators rated tens of kW and coupled to free-piston Stirling engines are presently viewed as promising candidates for long term generation of electric power in both space and terrestrial applications. Series capacitive cancellation of the internal inductive reactance of such alternators was considered a viable way to both increase power extraction and to suppress unstable modes of the thermodynamic oscillation. Idealized toroidal and cylindrical alternator geometries are used for a comparative study of the issues of specific mass and capacitive tuning, subject to stability criteria. The analysis shows that the stator mass of an alternator designed to be capacitively tuned is always greater than the minimum achievable stator mass of an alternator designed with no capacitors, assuming equal utilization of materials ratings and the same frequency and power to a resistive load. This conclusion is not substantially altered when the usually lesser masses of the magnets and of any capacitors are added. Within the reported stability requirements and under circumstances of normal materials ratings, this study finds no clear advantage to capacitive tuning. Comparative plots of the various constituent masses are presented versus the internal power factor taken as a design degree of freedom. The explicit formulas developed for stator core, coil, capacitor, and magnet masses and for the degree of magnet utilization provide useful estimates of scaling effects. Author (revised)

(DE93-013765; SAND-93-0539C; CONF-930445-12) Avail: CASI HC A03/MF A01

Real-time gray-scale correlation in the spatial domain has been demonstrated previously using an acousto-optical (AO) correlator. This work demonstrates normalized gray-scale correlation as implemented on an AO correlator system capable of operating at real-time video rates. The motivation for using normalized gray-scale correlation is presented. The normalized correlation algorithm as implemented on the AO correlator is detailed. The entire real-time AO correlator system is described including the electronic support hardware and the user interface. Since normalization requires a division operation, system numerical precision issues are addressed. Test results obtained in non-real time experiments are presented. DOE

(DE92-644548; JINR-R-13-91-282) Avail: CASI HC A02 (US Sales Only)

A direct current transducer based on magnetic comparison of direct currents is discussed. The principle of operation of the transducer is considered, its blockdiagram, circuit diagram, and technical solutions for some of its units are given. General zero drift of the transducer, reduced to the current measured, does not exceed 0.1 A. The output voltage of the transducer is 10 V at the rated value of the current measured. DOE

ON THE STABILITY OF STATIONARY REGIMES IN A DISTRIBUTED AUTOVIBRATION SYSTEM WITH EXTERNAL FEEDBACK [OB USTOJCHIVOSTI STATSIONARNYKH REZHIMOV V RASPREDELENNOJ AVTOKOLEBATEL'NOJ SISTEME S VNESHNEJ SVYAZ'YU]
N. I. Ajzatskij and A. O. Ostrovskij 1991 15 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-620979; KFTI-91-39) Avail: CASI HC A03 (US Sales Only)

A numerical investigation of the distributed autogenerator stationary state stability is described. It was shown that the realization of stable stationary excitation of resonance frequency vibrations strongly depends on the normalized nonlinear amplifier length (l). At small l-values such a regime is unstable, but with increasing of this parameter, the autovibration system becomes stable. Linear characteristics of stationary regime instability are found. It was shown that in the considered range of dynamic system non-equilibrium parameter changes, two stationary generation regimes on different frequencies correspond to the same autogenerator transmitting characteristics. A process is explained for fabricating a detector array in a layer of semiconductor material on one substrate and an integrated readout circuit in a layer of semiconductor material on a separate substrate in order to select semiconductor material for optimum performance of each structure, such as GaAs for the detector array and Si for the integrated readout circuit. The detector array layer is lifted off its substrate, laminated on the metallized surface on the integrated surface, etched with reticulating channels to the surface of the integrated circuit, and provided with interconnections between the detector array pixels and the integrated readout circuit through the channels. The adhesive material for the lamination is selected to be chemically stable to provide electrical and thermal insulation and to provide stress release between the two structures fabricated in semiconductor materials that may have different coefficients of thermal expansion.

DIELECTRIC RESONATOR Patent
Arthur Ballato, inventor (to Army) 1 Apr. 1986 5 p Filed 11 Feb. 1985 Supersedes AD-D011573
(US-Patent-4,580,116; US-Patent-Appl-SN-699990;
US-Patent-Class-333-234; US-Patent-Class-333-219;
US-Patent-Class-333-235; Int-Patent-Class-H01P-7/10) Avail: US Patent and Trademark Office

This invention relates generally to signal oscillators and more particulary to microwave and millimeter wave oscillators comprised of dielectric resonators. A method and means for producing a zero temperature coefficient for providing frequency stabilization as well as adjusting the frequency at a particular temperature of a dielectric resonator element mounted on a substrate and having a dielectric disc affixed to the top of the resonator element is discussed. A zero temperature coefficient is obtained by selectively choosing the thickness of the dielectric disc depending upon the temperature coefficients of the constituent material of both the disc and resonator element. The operating frequency at a given temperature is furthermore adjusted by including two mutually contiguous patterns of metallization on the top surface of the resonator element and the bottom surface of the dielectric disc and thereafter rotating the disc so that a predetermined percentage of overlap between the two patterns exists.

EFFECT OF EFFECTIVE MASS DIFFERENCES ON THE TUNNELING CURRENT-VOLTAGE BEHAVIOUR OF A RESONANT DIODE IN THE PRESENCE OF SPACE CHARGE BUILD-UP
F. B. Sigalo and S. Y. Mensah Sep. 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613817; IC-92/300) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

A theoretical study of the effect of differences in effective masses for electrodes and well, on the characteristics of tunneling current against bias voltage, in the presence of charge build-up was conducted. It is observed that balanced effective mass (i.e M(sup *)(sub l) = m(sup *)(sub r)), where m(sup *)(sub l) and m(sup *)(sub r) are the effective masses for electrode and well, respectively, results in the normal expected behaviour of rising current with increased bias voltage. Whereas, a positive difference causes charge saturation and zero current change, while a negative difference invokes excess current flow. DOE

All layers of mask set 2 were received prior to Feb. 1. A photograph of the overall reticle layout is shown. There are 16 reticles per 1 in. wafer and 9 different chips per reticle for a total of 149 chips of which about 120 are expected to be usable (about 30 chips are too close to the wafer edge). On this mask set, we concentrated on straightforward arrays of tips of different sizes oriented in such a way that they could be conveniently packaged onto TO-8 headers. In the previous experiments, we found the most significant impediment to consistency in testing was the bonding, die-attaching, and packaging. DTIC

A STUDY OF DC-DC CONVERTERS WITH MCTS FOR ARCJET POWER SUPPLIES
Thomas A. Stuart, Roger J. King, and Brian J. Masserant Jan. 1993 78 p
(Grant NAG3-1102)
(NASA-CR-193457; NAS 1.26:193457) Avail: CASI HC A05/MF A01

Many arcjet DC power supplies use PWM full bridge converters with large arrays of parallel FET's. This report investigates an alternative supply using a variable frequency series resonant converter with small arrays of parallel metal oxide semiconductor controlled thyristors (MCT's). The reasons for this approach are to: increase reliability by reducing the number of switching devices; and decrease the surface mounting area of the switching arrays. The variable frequency series resonant approach is used because the relatively slow switching speed of the MCT precludes the use of PWM. The 10 KW converter operated satisfactorily with an efficiency of over 91 percent. Test results indicate this efficiency could be increased further by additional optimization of the series resonant inductor. Author (revised)

DEVELOPMENT OF COMMERCIALLY VIABLE HIGH-T(SUB c) Bi-2223 SUPERCONDUCTOR TAPES
U. Balachandran, C. A. Youngdahl, P. Haldar (Intermagnetics General Corp., Guilderland, NY.), and L. R. Motowidlo (IGC/Advanced Supercomputers, Inc., Waterbury, CT.) Feb. 1993 9 p Presented at the 5th Annual International Superconductor Applications Conference, San Jose, CA, 1-3 Feb. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE93-009966; ANL/MCT/CP-78926; CONF-930235-1) Avail: CASI HC A02

Long lengths of flexible Ag-clad Bi-2223 Superconductors have been fabricated by the powder-in-tube technique using prereacted, poly-phase, Pb-doped Bi-Sr-Ca-Cu-O powders. At the temperature of liquid helium (4.2 K), improved process conditions yielded transport critical current density (J(sub c)) values greater than 10(exp 5) A/sq cm at zero field; at the temperature of liquid nitrogen (77K), the J(sub c) values of short tape samples exceeded 4(10)(exp 4) A/sq cm. Rolled tapes are cut into lengths up to 2 m in length and are used in parallel to fabricate small superconducting pancake coils by the 'wind-and-react' technique. The coils are characterized at 77 K and 4.2 K. The J(sub c) of the coils are up to 80% of the short, rolled sample result at 77 K. The coils exhibited these results even after being cooled and warmed several times between ambient, 77 K, and 4.2 K indicating their stability following thermal cycling. DOE

ELECTROMECHANICAL BATTERIES AND THE ELECTRIC LOCOMOTIVE
R. F. Post 21 Sep. 1992 4 p
(Contract W-7405-eng-48)
(DE93-013311; UCRL-ID-111855) Avail: CASI HC A01/MF A01

This technical note describes an electromechanical battery to be used as an electrical storage system for powering locomotives instead of traditional diesel-electric generators. The electromechanical battery would entail a high-speed rotor, supported by a magnetic suspension/bearing system, and carrying an integrally mounted generator/motor; the whole operating in an evacuated enclosure. The concept also includes the concept of modularity, i.e. using many relatively small units to build up a battery bank, in the same manner that ordinary batteries are used. This note emphasizes the rotor, its material, and its volumetric energy storage density. DOE

(DE93-011897; UCRL-JC-110977; CONF-920671-14) Avail: CASI HC A02/MF A01

Work is being done to develop a high pressure gas switch (HPGS) with picosecond risetimes for UWB applications. Pulse risetimes on the order of 200 picoseconds have been observed at 1 kHz prf and 1 atmosphere. Calculations show that switching closure times on the order of tens of picoseconds can be achieved at high pressures and higher electric fields. A voltage hold-off of 1 MV/cm has been measured at 10 atmospheres and several MV/cm appears possible with the HPGS. With these high electric field levels, energy storage of tens of Joules in a reasonably sized package is achievable. Initial HPGS performance has been characterized on the WASP pulse generator at LLNL. A detailed description of the switch used for initial testing is given. Switch recovery times of 1-ms have been measured at 1 atmosphere. Data on the switching uniformity, voltage hold-off recovery, and pulse repeatability, is presented. In addition, a physics switch model is described and results are compared with lab data. DOE

A number of node assignment schemes, both static and dynamic, are explored for the Algorithm to Architecture Mapping Model (ATAMM). The architecture under consideration consists of heterogeneous processors and implements dataflow models of real-time applications. Terminology is developed for heterogeneous computing. New definitions are added to the ATAMM for token and assignment classifications. It is proved that a periodic execution is possible for dataflow graphs. Assignment algorithms are developed and proved. A design procedure is described for satisfying an objective function in an heterogeneous architecture. Several examples are provided for illustration. APPLICATIONS OF SPECTROSCOPIC ELLIPSOMETRY TO MICROELECTRONICS Technical Report
E. A. Irene 4 May 1993 43 p
(Contract N00014-89-J-1178)
(AD-A265148) Avail: CASI HC A03/MF A01

Ellipsometry has been applied to problems in the microelectronics industry from the beginning in the 1960's. More recently spectroscopic ellipsometry has been introduced. In-situ during process ellipsometry offers great promise for monitoring and control of a wide variety of microelectronics processes. This review covers some applications in silicon technology such as oxidation, chemical vapor deposition, etching, interfaces, and new processing techniques such as plasma, ion beam, and rapid thermal, in an effort to demonstrate the kinds of crucial microelectronics information and processes that modern ellipsometry can access. The conclusion is that single wavelength ellipsometry alone is not sufficient; spectroscopic ellipsometry is required to establish the optimum ellipsometry measurement conditions. The future of ellipsometry in microelectronics is assessed. DTIC

RADIATION HARDNESS OF Mo/Si MULTILAYERS DESIGNED FOR USE IN A SOFT X RAY PROJECTION LITHOGRAPHY SYSTEM
D. P. Gaines, R. C. Spitzer, N. M. Ceglio, M. Krumrey, and G. Ulm Sep. 1992 21 p Presented at the Soft X Ray Projection Lithography Topical Meeting, Monterey, CA, 6-8 Apr. 1992
(Contract W-7405-eng-48)
(DE93-011879; UCRL-JC-111725; CONF-9204120-6) Avail: CASI HC A03/MF A01

A molybdenum silicon multilayer was irradiated with 13.4 nm radiation to investigate changes in multilayer performance under simulated Soft X-ray Projection Lithography (SXPL) conditions. The wiggler/undulator at the Berlin electron storage ring BESSY was used as a quasi-monochromatic source of calculable spectral radiant intensity and was configured to simulate an incident SXPL x-ray spectrum. The test multilayer received a radiant exposure of 240 J/sq mm in an exposure lasting 8.9 hours. The corresponding average incident power density was 7.5 mW/sq mm. The absorbed dose of 7.8 x 10(exp 10) J/kg (7.8 x 10(exp 12) rd) is equivalent to 1.2 times the dose that would be absorbed by a multilayer coating on the first imaging optic in a hypothetical SXPL system during one year of operation. Surface temperature increases did not exceed 2 C during the exposure. Normal incidence reflectance measurements at lambda(sub 0) = 13.4 nm performed prior to radiation exposure were in agreement with measurements performed after the exposure, indicating that no significant damage had occurred. DOE

CHARACTERIZATION OF THE PULSE TRANSFORMER Final Report
W. H. Mosterdijk Dec. 1992 32 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A263414; ISL-PML-1992-73) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report treats characterization of the pulse transformer at TNO PML Pulse Physics, Delft. The pulse transformer constitutes the final step of an energy compression system, called the Kapitza facility, and is able to amplify the current up to 24 times. The pulse transformer consists of a primary single layer winding of 24 turns which is enclosed by an aluminium secondary winding, consisting of one inner- and one outer which are coupled in parallel. Characterization means: determination of the electrical quantities, such as the ohmic resistance and the inductance of the primary and secondary windings. A current source able to deliver single-wave currents with adjustable frequencies was used. From the measurement it appears that the main inductances decrease and the ohmic resistances increase with increasing frequency. This is caused by differential currents, skin and proximity effect, and parasitic induced currents in aluminum secondary winding. DTIC

(DE93-620976; KFTI-91-30) Avail: CASI HC A03 (US Sales Only)

The dynamics of autovibration processes in a system of narrow-band autogenerators coupled in a distributive manner with delayed feedback is considered. A system of self-consistent equations describing the space-time dynamics of HF field excitation in coupled electrodynamic delaying structures is obtained. Numerical modelling shows that the coupling of the autogenerators leads to a decrease in the non-equilibrium parameter in a dynamic system compared with an isolated autogenerator. The effectiveness of electron beam energy transfer into electromagnetic radiation energy is defined. DOE

ASSESSMENT OF THE IMPACT OF HTSC'S ON SUPERCONDUCTING FAULT-CURRENT LIMITERS
R. F. Giese and M. Runde (Electric Power Research Inst., Trondheim, Norway.) 1993 8 p Presented at the 55th Annual American Power Conference, Chicago, IL, 13-15 Apr. 1993 Prepared in cooperation with

Energiforsyningens Forskningsinstitutt A/S, Trondheim, Norway
(Contract W-31-109-eng-38)
(DE93-009986; ANL/ES/CP-78917; CONF-930433-4) Avail: CASI HC A02/MF A01

The possible impact of nitrogen-cooled superconductors on the design and cost of superconducting fault-current limiters is assessed by considering the technical specifications such devices must meet and by comparing material properties of 77K and 4K superconductors. The main advantages of operating superconductors at 77K are that the refrigeration operating cost is reduced by a factor of up to 25 and the refrigeration capital cost is reduced by a factor of up to 10. The heat capacity is several orders of magnitude larger at 77K and at 4K. This phenomenon increases conductor stability against flux jumps but makes switching from the superconducting to the normal state slow and difficult. Therefore, a high critical current density, probably at least 10(exp 5) A/sq cm, is required. DOE

PROGRAMMABLE LOGIC DEVICES
J. L. Jacobs Apr. 1993 23 p
(Contract DE-AC04-76DP-00613)
(DE93-013117; KCP-613-5042) Avail: CASI HC A03/MF A01

Erasable programmable logic devices (EPLD's) were investigated to determine their advantages and/or disadvantages in Test Equipment Engineering applications. It was found that EPLD's performed as well as or better than identical circuits using standard transistor transistor logic (TTL). The chip count in these circuits was reduced, saving printed circuit board space and shortening fabrication and prove-in time. Troubleshooting circuits of EPLD's was also easier with 10 to 100 times fewer wires needed. The reduced number of integrated circuits (IC's) contributed to faster system speeds and an overall lower power consumption. In some cases changes to the circuit became software changes using EPLD's instead of hardware changes for standard logic. Using EPLD's was fairly easy; however, as with any new technology, a learning curve must be overcome before EPLD's can be used efficiently. The many benefits of EPLD's outweighed this initial inconvenience. DOE

PERFORMANCE CHARACTERISTICS OF THE INS 25.5-MHz SPLIT COAXIAL RFQ
N. Tokuda, S. Arai, A. Imanishi, T. Morimoto, S. Shibuya, and E. Tojyo Apr. 1992 4 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-753168; INS-920) Avail: CASI HC A01

The performance of the INS 25.5-MHz split coaxial RFQ was clarified through high-power and acceleration tests. The cavity operates stably at a duty factor of 20% and a peak power of 80 kW, generating an intervane voltage of 109.3 kV, the design value for ions with a charge-to-mass ratio of 1/30. Acceleration tests were conducted to study the performance of the vanes machined by means of the two-dimensionally cutting technique. The results show that the A(sub 10) coefficient of the electric field will be close to the one calculated by Crandall, and that the field in the radial matching section might be different from the designed one. IMPROVEMENT OF AZIMUTHAL HOMOGENEITY IN PERMANENT-MAGNET BEARING ROTORS
J. R. Hull, T. D. Rossing, T. M. Mulcahy, and K. L. Uherka 23 Oct. 1992 3 p Presented at the International Magnetics Conference, Stockholm, Sweden, 13-16 Apr. 1993
(Contract W-31-109-eng-38)
(DE93-009954; ANL/MCT/CP-77835; CONF-930416-2) Avail: CASI HC A01/MF A01

Permanent magnets that are levitated and rotating over a bulk high-temperature superconductor (HTS) form the basis of many superconducting bearing designs. Experiments have shown that the rotational-loss 'coefficient of friction' for thrust bearings of this type can be as low as 8 x 10(exp -6). While the loss mechanisms of such bearings are not well understood, the azimuthal homogeneity of the rotating permanent magnet is believed to play an important role in determining the loss. One possible loss mechanism is magnetic hysteresis in the HTS, where the energy loss E per cycle is derived from the critical state model and given by E = K (Delta B)(sup 3)/J(sub c) where K is a geometric coefficient, Delta B is the variation in magnetic field at the surface of the HTS experienced during a rotation of the levitated magnet, and J(sub c) is the critical current density of the HTS. It is clear that a small decrease in Delta B (i.e., decreasing the azimuthal inhomogeneity of the rotating magnetic field) could have profound effects on decreasing E and the rotational coefficient of friction. The role of Delta B is also expected to be significant in reducing losses from eddy currents and other mechanisms. Low rotational losses in HTS bearings have been demonstrated only for levitated masses of several grams. For practical bearings, it is important to obtain these low losses with larger levitated masses. There are two main routes toward decreasing Delta B. The first is to improve the alignment of the magnetic particles during fabrication and to maintain close tolerances on grinding angles during manufacture of the permanent magnet. The second, the subject of this paper, is to provide correctional procedures after the magnet is fabricated. DOE

ELECTRIC AND HYBRID VEHICLE SITE OPERATORS PROGRAM: THINKING OF THE FUTURE
1993 31 p
(Contract DE-FC07-91ID-13074)
(DE93-011231; DOE/ID-13074/T7) Avail: CASI HC A03/MF A01

Kansas State University, with support from federal, state, public, and private companies, is participating in the Department of Energy's Electric Vehicle Site Operator Program. Through participation in this program, Kansas State is displaying, testing, and evaluating electric or hybrid vehicle technology. This participation will provide organizations the opportunity to examine the latest EHV prototypes under actual operating conditions. KSU proposes to purchase one electric or hybrid van and two electric cars during the first two years of this five-year program. KSU has purchased one G-Van built by Conceptor Industries, Toronto, Canada and has initiated a procurement order to purchase two Soleq 1993 Ford EVcort station wagons. The G-Van has been signed in order for the public to be aware that this is an electric drive vehicle. Financial participants' names have been stenciled on the back door of the van. This vehicle is available for short term loan to interested utilities and companies. When other vehicles are obtained, the G-Van will be maintained on K-State's campus. DOE

A THERMAL IONIZATION MODEL FOR THE SUSTAINING PHASE OF LOCK-ON IN GaAs

H. P. Hjalmarson, F. J. Zutavern, G. M. Loubriel, M. T. Buttram, A. G. Baca, and L. A. Romero 1992 10 p Presented at the OE/LASE 1993: International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 16-23 Jan. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011558; SAND-92-2857C; CONF-930159-28) Avail: CASI HC A02/MF A01

Thermal ionization of electrons and holes is proposed as an explanation for the sustained phase of lock-on in semi-insulating GaAs. In this mechanism, thermal ionization leads to a current instability which drives the formation of current filaments. The model predicts bistable states: either a highly conductive on-state or weakly conductive off-state. The model predicts that a transition from the off-state to a filamentary-current on-state can be triggered by illumination in agreement with experiments using photoexcitation. DOE

THREE-CAVITY CIRCUIT STUDIES OF THE MARYLAND GYROKLYSTRON
C. D. Striffler, S. Tantawi, W. Main, B. Hogan, P. E. Latham, W. Lawson, U. V. Koc, H. W. Matthews, G. S. Nusinovich, and V. L. Granatstein 1992 4 p Presented at the 16th International LNAC Conference, Ottawa, Canada, 23-28 Aug. 1992
(Contract DE-FG05-91ER-40642)
(DE93-010173; CONF-9208109-80) Avail: CASI HC A01/MF A01

At the University of Maryland we have examined an X-Band TE(sub 01) mode three-cavity gyroklystron circuit that includes a tunable buncher cavity. The system parameters are: 425 kV, 100-200 A, pulse length approximately 1 (mu)s, operating frequency 9.85 GHz, and a beam alpha, upsilon(perpendicular)/upsilon(sub z), in the range 0.7-1.0. This circuit produced a maximum power of 27 MW at 32% efficiency and a gain of 36 dB. We will summarize the major results of the three-cavity systems, including recent output cavity configurations that were to affect the post-cavity interaction. DOE

RESIST MATERIALS DESIGN: BASE-CATALYZED CHEMICAL AMPLIFICATION
C. G. Willson, J. F. Cameron, S. A. MacDonald, C. P. Niesert, and J. M. Frechet 12 May 1993 16 p
(Contract N00014-91-J-1338)
(AD-A265286; TR-11-ONR) Avail: CASI HC A03/MF A01

The search for advanced resists that can provide the high density of circuits and high throughput required for the new generations of microelectronic devices requires that highly stable chemically amplified materials be developed. In view of the high susceptibility of resists, based on photoacid generation, to environmental contamination, resulting in lessened performance, a program aimed at the development of chemically amplified resists utilizing photobase generation has been undertaken. In a first approach, the photogenerated amines we developed in the first stage of this project were used as catalysts for the decarboxylation of totally new resist systems containing active carboxylic acid pendant groups. The resist materials could be developed to afford negative tone images through wet development in aqueous base, or positive tone images through dry development using a gas-phase silylation reaction followed by oxygen plasma etching. The first patterning experiments carried out with two new resists utilizing photogenerated base have confirmed the validity of the approach. DTIC

STATISTICAL PROCESS CONTROL IN THE HYBRID MICROELECTRONICS MANUFACTURING INDUSTRY: A NAVY VIEW POINT
Charles C. Azu, Jr. Apr. 1993 12 p
(AD-A265164) Avail: CASI HC A03/MF A01

The U.S. Navy is concerned with receiving high quality hybrid microelectronic circuits. The Navy recognizes that in order to obtain high quality circuits a manufacturer must have an effective statistical process control (SPC) program implemented. The implementation of effective SPC programs is an objective of the military hybrid microelectronics industry. Often the smaller sized manufacturers in the industry have little SPC implementation, while the larger manufacturers have practices originally developed for the control of other product lines outside the hybrid technology area. The industry recognizes that SPC programs will result in high quality hybrid microcircuits which the U.S. Navy requires. In the past, the goal of the industry had not been to put in effective process control methods, but to merely meet the government military standards on the quality of the hybrids they produce. This practice, at best, resulted in a 'hit or miss' situation when it comes to hybrid microcircuit assemblies meeting military standards. The U.S. Navy through its MicroCIM program has been challenging and working with the industry in the area of SPC practice methods. The major limitations so far have been a lack of available sensors for the real-time collection of effective SPC data on the factory floor. This paper will discuss the Navy's efforts in bringing about effective SPC programs in the military hybrid manufacturing industry. DTIC

LIMITED BANDWIDTH MICROWAVE FILTER Patent Application
Christen Rauscher, inventor (to Navy) 26 Feb. 1993 41 p
(AD-D015744; US-Patent-Appl-SN-025210; Navy-Case-74067) Avail: CASI HC A03/MF A01

A limited-bandwidth microwave transversal or recursive filter, compatible with microwave monolithic integrated circuit (MMIC) design requirements is described. The device comprises a means to split an incident signal into multiple parts for distribution among a plurality of input ports of frequency-selective feedforward and feedback network branches comprising filter elements and active devices so designed as to provide a desired degree and type of signal filtration. After filtration, the resulting signals from these branches are combined to form a composite filter output signal. DTIC

SUPERCONDUCTING SQUID AMPLIFIERS FOR IR DETECTORS AND OTHER APPLICATIONS, PHASE 2 Final Report
David Osterman 1 May 1993 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-C-0264)
(AD-A265447) Avail: CASI HC A03

The subject is a completed Phase 2 SBIR project to develop a superconducting analog multiplexer circuit. The intended application of the multiplexer is as a component of processing circuitry for a superconducting infrared focal plane array (IR FPA). Development of the IR FPA is in progress under a separate contract. Among the accomplishments that are described below is the fabrication and testing of a functioning, superconducting, 20-input multiplexer, appropriate for use with an IR FPA. The motivation for developing a superconducting multiplexer circuit derives primarily from the significant potential advantages of an all-superconducting IR FPA system, i.e. a system in which the detectors, as well as the associated processing circuitry, are superconducting. Section 3 reviews the subject of superconducting IR FPA's. Chief among the advantages of such systems is the potential for larger arrays with greater numbers of detectors than is now possible. DTIC

NONLINEAR ANALYSIS OF A MAGNICON OUTPUT CAVITY Interim Report
B. Hafizi, S. H. Gold, P. Sprangle, and W. M. Manheimer 9 Apr. 1993 49 p
(AD-A265342; NRL/MR/6790-93-7300) Avail: CASI HC A03/MF A01

A nonlinear analysis of the wave-particle interaction in the output cavity of a frequency-doubling magnicon amplifier is presented. The cavity is immersed in an axial magnetic field wherein electronics interact with a rotating TM210 mode via a gyro-resonant mechanism. The electron equations of motion and the wave equation for the radio-frequency field are derived and expressed in terms of scaled variables in order to study the general scaling of the output cavity. Single-electron, time-dependent simulation of the interaction in the cavity is performed to assess the accessibility and stability of high-efficiency states for an x-band magnicon. Results from multi-electron, steady-state simulation are presented to show the effect of spreads in electron beam radius, energy, and transverse momentum on the efficiency. DTIC

TIN WHISKERS IN ELECTRONIC CIRCUITS
Gary W. Stupian 20 Dec. 1992 24 p
(Contract F04701-88-C-0089)
(AD-A265917; TR-92(2925)-7; SMC-TR-93-18) Avail: CASI HC A03/MF A01

Fibrous, conducting 'whiskers' often grow on pure tin plating. These tin whiskers have, for many years, been known to pose a reliability problem in electronic circuitry; therefore, the use of pure tin coatings in any critical electronic application is not recommended. Despite the warnings of the experts, tin plating is still found on electronic and mechanical components and problems with whiskers still arise. This document summarizes what is known about the growth of tin whiskers. A number of factors (e.g., coating thickness, plating conditions) are thought to be important in determining whether whiskers will grow. Although tin whiskers have been investigated from some decades, there is still disagreement on the effects of virtually every coating parameter. There is no disagreement, however, on the essential fact that it is very difficult to predict with certainty whether whiskers will grow on any specific tin-plated component, which of course is the basis of the 'experts' advice not to use pure tin plating. If tin-plated components are found in an electronic system, replacement is the safest policy. Some additional recommendations to minimize risk are presented here that may be of use in situations in which replacement of all suspect components is not the option of choice because of cost or schedule constraints. SYNTHESIS AND ELECTRONIC PROPERTIES OF NANOPHASE SEMICONDUCTOR MATERIALS Report, 1 Jun. 1992 - 31 May 1993
Michael J. Sailor 25 May 1993 13 p
(Contract N00014-92-J-1810)
(AD-A265287) Avail: CASI HC A03/MF A01

The objective of the research effort is to understand and learn to control the morphologic and electronic properties of electrodeposited nanophase semiconductors. The initial work has focused on electrodeposition of nanophase CdSe, using a sequential monolayer deposition technique that we are developing. We are currently extending the synthesis phase of this project into silicon, silicon carbide, and phosphor materials. This work also encompasses studying semiconductor electrodeposition into materials with restricted dimensions, such as microporous alumina and porous silicon membranes. By growing films with very small grain sizes, we hope to produce and study materials that display unusual electronic or luminescent effects. We are primarily interested in the electronic properties of the II-VI and group IV materials, for potential applications in nanoscale electronics and optical detector technologies. The phosphors are being studied for their potential as efficient high-resolution display materials. DTIC

LOW COST HIGH EFFICIENCY GaAs MONOLITHIC RF MODULE FOR SARSAT DISTRESS BEACONS Final Report, 11 Jul. 1989 - 10 Nov. 1991
W. C. Petersen, D. P. Siu, and H. F. Cook Dec. 1991 101 p
(Contract NAS3-25712; SBIR-14.03-6642)
(NASA-CR-194235; NAS 1.26:194235) Avail: CASI HC A06/MF A02

Low cost high performance (5 Watts output) 406 MHz beacons are urgently needed to realize the maximum utilization of the Search and Rescue Satellite-Aided Tracking (SARSAT) system spearheaded in the U.S. by NASA. Although current technology can produce beacons meeting the output power requirement, power consumption is high due to the low efficiency of available transmitters. Field performance is currently unsatisfactory due to the lack of safe and reliable high density batteries capable of operation at -40 C. Low cost production is also a crucial but elusive requirement for the ultimate wide scale utilization of this system. Microwave Monolithics Incorporated (MMInc.) has proposed to make both the technical and cost goals for the SARSAT beacon attainable by developing a monolithic GaAs chip set for the RF module. This chip set consists of a high efficiency power amplifier and a bi-phase modulator. In addition to implementing the RF module in Monolithic Microwave Integrated Circuit (MMIC) form to minimize ultimate production costs, the power amplifier has a power-added efficiency nearly twice that attained with current commercial technology. A distress beacon built using this RF module chip set will be significantly smaller in size and lighter in weight due to a smaller battery requirement, since the 406 MHz signal source and the digital controller have far lower power consumption compared to the 5 watt power amplifier. All the program tasks have been successfully completed. The GaAs MMIC RF module chip set has been designed to be compatible with the present 406 MHz signal source and digital controller. A complete high performance low cost SARSAT beacon can be realized with only additional minor iteration and systems integration. Derived from text

AN EXPERIMENTAL INVESTIGATION OF HIGH-SPEED WATER-ENTRY FOR FULL-SIZE AND SCALE-MODEL POINTED NOSE VEHICLES
J. K. Cole, C. E. Hailey, W. T. Gutierrez, and M. T. Ferrario (Sandia National Labs., Livermore, CA.) Feb. 1993 29 p
(Contract DE-AC04-76DP-00789)
(DE93-008491; SAND-92-2579) Avail: CASI HC A03/MF A01 (US Sales Only)

A full-scale water-entry test of a pointed nose penetrator was conducted at the Kauai Test Facility in February 1991. The vehicle was rocket boosted to enter the water at a velocity of 301 m/s and an impact angle of -29 deg from the horizontal. During the test, triaxial accelerations and base pressures were recorded by a rugged, onboard data acquisition system. In June 1991, a scale-model water-entry test program was conducted at the Naval Surface Warfare Center's (NSWC) Hydroballistics Facility. Each scale model contained an onboard, miniature, data acquisition system which recorded axial acceleration and base pressure during water entry. The data acquisition system was specially designed to survive high-speed water entry and to fit inside models with base diameters as small as 3.81 cm. The NSWC test program was conducted for impact velocities ranging from 96-319 m/s and impact angles of -27 deg and -35 deg. This report compares the full-scale and scale-model acceleration histories and minimum cavity pressures. The validity of using Froude scaling is discussed and relationships are presented for minimum cavity pressure and maximum deceleration as a function of entry velocity and angle. DOE

UNI-DIRECTIONAL WAVES OVER SLOWLY VARYING BOTTOM. PART 1: DERIVATION OF A KdV-TYPE OF EQUATION
E. W. C. vanGroesen and S. R. Pudjaprasetya (Bandung Inst. of Tech., Indonesia.) 29 Nov. 1992 27 p
(MEMO-1098; ETN-93-94311) Avail: CASI HC A03/MF A01

A new version of forced Korteweg-de Vries (KdV) equation for undirectional surface over an uneven bottom is derived. The Hamiltonian formulation of the exact equations for surface waves are reviewed. The approximation leading to the bidirectional Boussinesq equation is described. The KdV equation for the ease of constant bottom is derived in suitable way for the generalization to uneven bottom. The linear, lowest order equation, which also shows the special properties of the spatial dependent map gamma(x), is investigated. The forced KdV equation is derived for the elevation itself and the forcing is investigated in the case of localized bottom variations. The forcing equation derived allows precise estimation for its order of magnitude when compared to the usual KdV equation. In part 2 of the investigation, the distortion of solitary waves is studied. LATTICE GAS HYDRODYNAMICS: THEORY AND SIMULATIONS
B. Hasslacher 1993 10 p
(Contract DE-FG03-89ER-13991)
(DE93-013297; DOE/ER-13991/2) Avail: CASI HC A02/MF A01

The first successful application of a microscopic analogy to create a skeleton cellular automaton and analyze it with statistical mechanical tools, was the work of Frisch, Hasslacher and Pomeau on the Navier-Stokes equation in two and three dimensions. This has become a very large research area with lattice gas models and methods being used for both fundamental investigations into the foundations of statistical mechanics and a large number of diverse applications. This present research was devoted to enlarging the fundamental scope of lattice gas models and proved successful. Since the beginning of this proposal, cellular automata have been constructed for statistical mechanical models, fluids, diffusion and shock systems in fundamental investigations. In applied areas, there are now excellent lattice gas models for complex flows through porous media, chemical reaction and combustion dynamics, multiphase flow systems, and fluid mixtures with natural boundaries. With extended cellular fluid models, one can do problems with arbitrary pairwise potentials. Recently, these have been applied to such problems as non-newtonian or polymeric liquids and a mixture of immiscible fluids passing through fractal or spongelike media in two and three dimensions. This proposal has contributed to and enlarged the scope of this work. DOE

A GRID GENERATION METHOD TO CALCULATE THE FLOW FIELD IN A THREE-DIMENSIONAL CASCADE OF BLADES [SANJIGEN YOKURETSU NAGARE KEISAN NO TAMENO KOUSHI KEISEI]
Kenji Inoue May 1992 10 p In JAPANESE
(NAL-TR-1158; JTN-93-80435; DE93-767978) Avail: CASI HC A02/MF A01

A method is described for generating boundary fitted grids to calculate the flow field across a three dimensional cascade of blades placed radially in the axially symmetric space between the hub and casing. Successive application of a series of stretching and conformal transformation maps one-period domain of the cascade onto a box in computational space. The grid in physical space is then obtained by inverse transformation of the grid points in computational space, being an H-type grid and having a periodicity which includes the inclination of grid lines at the periodic boundary. SOLVING THE INVERSE PROBLEM FOR INCOMPRESSIBLE POTENTIAL FLOW THROUGH TWO-DIMENSIONAL CASCADES [NIJIGEN YOKURETSU WO SUGIRU HIASSHUKU POTENSHARU NAGARE NO GYAKUMONDAI]
Kenji Inoue Jun. 1992 12 p In JAPANESE
(NAL-TR-1162; JTN-93-80436; DE93-767979) Avail: CASI HC A03/MF A01

A method to solve the inverse problem for incompressible potential flow through two-dimensional cascades is described. This method enables the determination of blade profiles which realize a flow possessing the prescribed surface speed distribution, solidity, and incident angle. The employed method reduces the problem to one for conformal mappings, with the unknown coefficients used in the mappings being determined by computational numerical iterations. A sample calculation is conducted for a representative compressor cascade having known flow conditions, and the cascade's original configuration is well simulated. In addition, the method is also applied to obtain blade profiles for the same surface speed distribution but at a different solidity or incident angle. Author (NASDA)

CORNER VORTEX SUPPRESSOR Patent Application
Promode R. Bandyopadhyay, inventor (to Navy) 22 Feb. 1993 12 p
(AD-D015772; US-Patent-Appl-SN-020940) Avail: CASI HC A03/MF A01

The general purpose and object of this invention is to provide means for suppressing corner vortex generation and/or growth without the necessity for applying continuous suction at the corner and/or by providing structural faring or filleting at the corner. Another object of the invention is to provide a passive structure for alleviating the adverse effects of a corner vortex, and providing a means for accomplishing this result that is amenable to retrofitting and which does not require substantial changes in the cross sectional configuration of the structure as would be the case in faring or filleting the corner. This technique is passive and thus involves no suction of the fluid. DTIC

HYGROSCOPIC ABSORPTION TO FALLING FILMS: THE EFFECTS OF THE CONCENTRATION LEVEL M.S. Thesis

Genick Meyerson Dec. 1991 137 p
(ITN-93-85198) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The aim was to investigate analytically the influence of the concentration of the absorbate in a liquid film on the process of vapor absorption into the film. The theoretical approach is an extension of earlier work on isothermal absorption and on non-isothermal absorption under conditions of low concentration and short contact time. Following presentation of a model for isothermal absorption, a model for non-isothermal absorption is developed which considers simultaneous heat and mass transfer. The main assumptions in the model are short exposure time, uniform film thickness and constant physical properties. In contrast to the low-concentration case, the governing diffusion equation is nonlinear with respect to absorbate concentration; an analytical solution for the equation was established; it leads to a pair of algebraic equations for isothermal absorption and to a set of four algebraic equations for non-isothermal absorption. Computer-calculated numerical solutions are presented for both cases. Theories based on the assumption of low concentration can lead to inaccurate mass-transer rate estimation; it was found that the mass-transfer rate increases with concentration, so that boundary layer growth is faster in a high-concentration film than in one with low concentration. Coupling between heat transfer and mass transfer leads to reduced mass transfer in the non-isothermal case. ISA

SCHLIEREN PHOTOGRAPHS AND INTERNAL PRESSURE DISTRIBUTIONS FOR THREE-DIMENSIONAL SIDEWALL-COMPRESSION SCRAMJET INLETS AT A MACH NUMBER OF 6 IN CF4

Scott D. Holland Washington Aug. 1993 143 p
(RTOP 506-40-41-02)
(NASA-TM-4479; L-17206; NAS 1.15:4479) Avail: CASI HC A07/MF A02

Three-dimensional sidewall-compression scramjet inlets with leading-edge sweeps of 30 deg and 70 deg were tested in the Langley Hypersonic CF4 Tunnel at a Mach number of 6 and a free-stream ratio of specific heats of 1.2. The parametric effects of leading-edge sweep, cowl position, contraction ratio, and Reynolds number were investigated. The models were instrumented with static pressure orifices distributed on the sidewalls, baseplate, and cowl. Schlieren movies were made of selected tunnel runs for flow visualization of the entrance plane and cowl region. Although these movies could not show the internal flow, the effect of the internal flow on the external flow was evident by way of spillage. The purpose is to provide a preliminary data release for the investigation. The models, facility, and testing methods are described, and the test matrix and a tabulation of tunnel runs are provided. Line plots highlighting the stated parametric effects and a representative set of schlieren photographs are presented without analysis. Author (revised)

VISCOUS FLOW SIMULATION USING AN UPWIND METHOD FOR HEXAHEDRAL BASED ADAPTIVE MESHES Final Report, Apr. 1992 - Jan. 1993

Michael J. Aftosmis 1 Mar. 1993 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2404)
(AD-A265901; WL-TR-93-3015) Avail: CASI HC A04

Details of an adaptive, high resolution, upwind algorithm for the simulation of viscous flows on unstructured hexahedral meshes are presented. The method used a TVD scheme for modeling the inviscid terms while the viscous terms rely upon central differencing. Grid adaptation is achieved through directional division of hexahedral cells in response to flow features. The discussion focuses primarily on details of the new viscous discretization and evaluates it through example problems, analysis, and mathematical proof. Several issues facing the development of upwind schemes on adaptive, unstructured meshes are prominently discussed. The test cases examine issues of consistency and mesh convergence of the adaptive methodology and the ability of the adaptation to accurately resolve flows which require detailed resolution of subtle flow features. These examples point out several general issues regarding the interaction of the upwind inviscid discretization with the centrally differenced viscous terms, especially near inviscid stagnation points, and within the boundary layer itself. A technique for avoiding the appearance of anomalous solutions in such regions is presented and discussed. DTIC

ATOMIZATION CHARACTERISTICS OF A PREFILMING AIRBLAST ATOMIZER [JITSUYOU KIRYUU BIRYUUKA NENRYOU NOZURU NO BIRYUUKA TOKUSEI]

Shigeru Hayashi, Atsushi Koito, and Manabu Hishiki Jan. 1992 14 p In JAPANESE
(NAL-TM-644; JTN-93-80422) Avail: CASI HC A03/MF A01

The size distribution of water test sprays generated by a prefilming airblast atomizer used for aeroengines was measured in swirling and non-swirling flows with the well established laser scattering particle sizing technique. Atomizing air velocity (or pressure difference) was varied in a range wider than the conditions of actual engines. The Sauter Mean Diameter (SMD) decreased at approximately a 1.5 power of the atomizing air velocity, being a higher velocity index than the previously reported values of 1 to 1.2. It was unexpectedly found that the effect of the liquid/air flow ratio was small. Since swirling flow increased the SMD at lower air velocities yet decreased it at higher ones, it is suggested that the reverse flow near the nozzle pintle adversely affects atomization. THE NONLINEAR EVOLUTION OF MODES ON UNSTABLE STRATIFIED SHEAR LAYERS Final Report

Nicholas Blackaby (Manchester Univ., England.), Andrew Dando (Manchester Univ., England.), and Philip Hall (Manchester Univ., England.) Washington NASA Jun. 1993 45 p Submitted for publication Sponsored in part by Science Research Council

(Contract NAS1-19480; RTOP 505-90-52-01)

(NASA-CR-191492; NAS 1.26:191492; ICASE-93-36) Avail: CASI HC A03/MF A01

The nonlinear development of disturbances in stratified shear flows (having a local Richardson number of value less than one quarter) is considered. Such modes are initially fast growing but, like related studies, we assume that the viscous, non-parallel spreading of the shear layer results in them evolving in a linear fashion until they reach a position where their amplitudes are large enough and their growth rates have diminished sufficiently so that amplitude equations can be derived using weakly nonlinear and non-equilibrium critical-layer theories. Four different basic integro-differential amplitude equations are possible, including one due to a novel mechanism; the relevant choice of amplitude equation, at a particular instance, being dependent on the relative sizes of the disturbance amplitude, the growth rate of the disturbance, its wavenumber, and the viscosity of the fluid. This richness of choice of possible nonlinearities arises mathematically from the indicial Frobenius roots of the governing linear inviscid equation (the Taylor-Goldstein equation) not, in general, differing by an integer. The initial nonlinear evolution of a mode will be governed by an integro-differential amplitude equations with a cubic nonlinearity but the resulting significant increase in the size of the disturbance's amplitude leads on to the next stage of the evolution process where the evolution of the mode is governed by an integro-differential amplitude equations with a quintic nonlinearity. Continued growth of the disturbance amplitude is expected during this stage, resulting in the effects of nonlinearity spreading to outside the critical level, by which time the flow has become fully nonlinear. DEVELOPMENT OF A DELAUNAY-BASED ADAPTION SCHEME WITH APPLICATIONS TO COMPLEX THREE-DIMENSIONAL ROTATIONAL FLOWS Ph.D. Thesis

Todd Jay Mitty 1993 139 p

Avail: Univ. Microfilms Order No. DA9311205

In order to compute accurate numerical solutions, it is necessary to maintain a small discretization error. This error may be controlled by adjusting the spacing between discrete points. However, it is preferable to selectively choose locations for such alterations rather than affect the entire domain. This leads to the notion of solution adaptation. A new solution adaptive technique was developed for solving the Euler equations within Delaunay tessellated, three dimensional, computational domains possessing planar boundaries. Mesh generation and solution adaptive mesh enrichment were achieved through application of the Bowyer/Watson algorithm, and resolution criteria were explored to determine the set of adapted points. The example of a reflecting oblique shock wave flow was used to validate the method. The other aspect of this research involved the application of the solution adaption method to supersonic inviscid rotational flows modeled by introducing vorticity through an inlet flow velocity distribution. The extent to which this model represents shock wave/boundary layer interactions was examined by comparing the solution adapted predictions with corresponding experimental data and published viscous computations for a 20 deg fin at nominal Mach numbers of both 3 and 4. The solution adaptation provided well resolved inviscid solutions which were sufficiently accurate to allow testing of the hypothesis that inviscid rotational features dominate the shock wave/boundary layer interaction flows. EXPERIMENTAL STUDY OF MULTIPLE DROPLET EVAPORATIVE COOLING Final Report, Dec. 1992

H. Dawson and M. diMarzo Apr. 1993 115 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant NANB1H1173)

(PB93-198463; REPT-92-1; NIST/GCR-93/624) Avail: Issuing Activity (National Technical Information Service (NTIS))

The purpose of the experimental study was to quantify the transient evaporative cooling of a radiantly heated, low thermal conductivity material subject to a random impingement of water droplets. Specifically, the transient behavior and spatial distribution of the surface temperature were investigated over a range of initial surface temperatures and impinging mass fluxes. Additionally, it was desired to draw some conclusions about the important parameters in the evaporative cooling phenomenon and about evaporative cooling generally. A concurrent goal of the research was to continue development of the infrared thermography and digital image analysis techniques and equipment employed in the data acquisition system. NTIS

A DYNAMICALLY ADAPTIVE MESH METHOD FOR INTERNAL FLOWS Ph.D. Thesis

John William Slater 1992 204 p

Avail: Univ. Microfilms Order No. DA9311535

A dynamic solution adaptive mesh method was implemented into a finite-volume numerical method for solving unsteady flow fields described by the two-dimensional, unsteady, Navier-Stokes and Euler equations. The objective was to improve the resolution and accuracy of solutions which contained flow gradients which varied in strength and position with time. Variational principles were used to formulate the mesh equations with which meshes were generated to have the desired smoothness, orthogonality, and volume adaption qualities. The adaption of the mesh to the flow solution was driven by the presence of flow gradients. The dynamics of the mesh was accounted for in the flow equations through the mesh speeds. A comparison was made between one approach which computed the mesh speeds from a backwards time differences of the mesh and another approach which computed the mesh speeds from a system of mesh speed equations which were derived from the time differentiation of the mesh equations. The dynamically adaptive mesh method was demonstrated for model problems involving solution and boundary dynamics, inviscid flows in a converging-diverging noble, viscous boundary-layer flows over flat plates, and viscous flows in a transonic diffuser. It was found that the approach using the mesh speed equations was more accurate than the approach using the time-differenced mesh speeds. There was difficulty is obtaining proper clustering of the meshes for viscous flows. Dissert. Abstr.

FLOWFIELD STRUCTURE OF SWEPT SHOCK WAVE/TURBULENT

BOUNDARY-LAYER INTERACTIONS Ph.D. Thesis
Farrukh Sabbah Alvi 1992 270 p
Avail: Univ. Microfilms Order No. DA9311584

A parametric experimental study was conducted to investigate the flowfield structure of sharp fin-generated swept shock wave/turbulent boundary-layer interactions. Two sets of experiments utilizing the conical shadowgraphy and PLS (Planar Laser Scattering) techniques were used to nonintrusively study the flowfield. This study was unique in that both these techniques took advantage of the natural quasiconical symmetry of these interactions. A broad range of interaction strengths, from barely separated to very strongly separated, was covered in both sets of experiments. The conical shadowgraphy experiments covered freestream Mach numbers of 2.5, 3, 3.5, and 4, while the PLS experiments were conducted at freestream Mach numbers of 3 and 4. The flowfield structure was visualized with a high degree of resolution and several new flowfield features were observed. By combining the results from these two experiments with previous results (mainly consisting of surface flowfield studies), a detailed physical model was constructed for the present class of interactions in the appropriate conical reference frame. This physical model is presented and discussed in terms of six detailed flowfield maps. Several new flowfield regime boundaries associated with the newly observed features were also defined. Finally, scaling laws, correlating the interaction growth to the appropriate interaction strength parameters, are also presented. Dissert. Abstr.

EVALUATION OF DUAL FLOW THRUST VECTORED NOZZLES WITH EXHAUST STREAM IMPINGEMENT MS Thesis Final Technical Report, Oct. 1990 - Jul. 1991
Thomas W. Carpenter 1991 106 p
(Contract NCC2-686)
(NASA-CR-193292; NAS 1.26:193292) Avail: CASI HC A06/MF A02

The main objective of this project was to predict the expansion wave/oblique shock wave structure in an under-expanded jet expanding from a convergent nozzle. The shock structure was predicted by combining the calculated curvature of the free pressure boundary with principles and governing equations relating to oblique shock wave and expansion wave interaction. The procedure was then continued until the shock pattern repeated itself. A mathematical model was then formulated and written in FORTRAN to calculate the oblique shock/expansion wave structure within the jet. In order to study shock waves in expanding jets, Schlieren photography, a form of flow visualization, was employed. Thirty-six Schlieren photographs of jets from both a straight and 15 degree nozzle were taken. An iterative procedure was developed to calculate the shock structure within the jet and predict the non-dimensional values of Prandtl primary wavelength (w/rn), distance to Mach Disc (Ld) and Mach Disc radius (rd). These values were then compared to measurements taken from Schlieren photographs and experimental results. The results agreed closely to measurements from Schlieren photographs and previously obtained data. This method provides excellent results for pressure ratios below that at which a Mach Disc first forms. Calculated values of non-dimensional distance to the Mach Disc (Ld) agreed closely to values measured from Schlieren photographs and published data. The calculated values of non-dimensional Mach Disc radius (rd), however, deviated from published data by as much as 25 percent at certain pressure ratios. Derived from text

NEW DEVELOPMENTS IN THE METHOD OF SPACE-TIME CONSERVATION ELEMENT AND SOLUTION ELEMENT: APPLICATIONS TO THE EULER AND NAVIER-STOKES EQUATIONS
Sin-Chung Chang Jun. 1993 99 p Presented at the second US National Congress on Computational Mechanics, 16-18 Aug. 1993; sponsored by the US Association for Computational Mechanics
(RTOP 505-62-52)
(NASA-TM-106226; E-7943; NAS 1.15:106226) Avail: CASI HC A05/MF A02

A new numerical framework for solving conservation laws is being developed. This new approach differs substantially in both concept and methodology from the well-established methods--i.e., finite difference, finite volume, finite element, and spectral methods. It is conceptually simple and designed to avoid several key limitations to the above traditional methods. An explicit model scheme for solving a simple 1-D unsteady convection-diffusion equation is constructed and used to illuminate major differences between the current method and those mentioned above. Unexpectedly, its amplification factors for the pure convection and pure diffusion cases are identical to those of the Leapfrog and the DuFort-Frankel schemes, respectively. Also, this explicit scheme and its Navier-Stokes extension have the unusual property that their stabilities are limited only by the CFL condition. Moreover, despite the fact that it does not use any flux-limiter or slope-limiter, the Navier-Stokes solver is capable of generating highly accurate shock tube solutions with shock discontinuities being resolved within one mesh interval. An accurate Euler solver also is constructed through another extension. It has many unusual properties, e.g., numerical diffusion at all mesh points can be controlled by a set of local parameters. INVERTING ULTRASONIC DATA ON SOLID/FLUID MIXTURES FOR BIOT-GASSMANN PARAMETERS
J. G. Berryman and D. E. Lumley (Stanford Univ., CA.) Feb. 1993 12 p Presented at the 2nd International Conference on Mathematical and Numerical Aspects of Wave Propagation (SIAM), Newark, DE, 7-10 Jun. 1993
(Contract W-7405-eng-48)
(DE93-011952; UCRL-JC-112052; CONF-9306142-1) Avail: CASI HC A03/MF A01

Although the Biot-Gassmann equations are known to predict acoustic data for water-saturated glass bead packings very well, these equations often seem to give anomalous results for naturally occurring rocks. The theory shows that, as the compressibility of the pore fluid increases, the inverse of the coefficients C and M in Biot's equations should increase linearly, and the theory also gives definite predictions about the values of the slope and intercept of the resulting lines. Although the anticipated linear behavior is observed in real data, the values of the slopes are smaller than expected for some rocks. Therefore, the process of inverting this data for the desired coefficients must incorporate other physical constraints and then produces, not a single value but rather, a range of possible values for each coefficient. FORCE2: A STATE-OF-THE-ART TWO-PHASE CODE FOR HYDRODYNAMIC CALCULATIONS
Jianmin Ding, R. W. Lyczkowski, and S. W. Burge (Babcock and Wilcox Co., Alliance, OH.) Feb. 1993 9 p Presented at the 12th International Conference on Fluidized-Bed Combustion, San Diego, CA, 8-13 May 1993
(Contract W-31-109-eng-38)
(DE93-010661; ANL/MCT/CP-76429; CONF-930521-5) Avail: CASI HC A02/MF A01

A three-dimensional computer code for two-phase flow named FORCE2 has been developed by Babcock and Wilcox (B & W) in close collaboration with Argonne National Laboratory (ANL). FORCE2 is capable of both transient as well as steady-state simulations. This Cartesian coordinates computer program is a finite control volume, industrial grade and quality embodiment of the pilot-scale FLUFIX/MOD2 code and contains features such as three-dimensional blockages, volume and surface porosities to account for various obstructions in the flow field, and distributed resistance modeling to account for pressure drops caused by baffles, distributor plates and large tube banks. Recently computed results demonstrated the significance of and necessity for three-dimensional models of hydrodynamics and erosion. This paper describes the process whereby ANL's pilot-scale FLUFIX/MOD2 models and numerics were implemented into FORCE2. A description of the quality control to assess the accuracy of the new code and the validation using some of the measured data from Illinois Institute of Technology (UT) and the University of Illinois at Urbana-Champaign (UIUC) are given. It is envisioned that one day, FORCE2 with additional modules such as radiation heat transfer, combustion kinetics and multi-solids together with user-friendly pre- and post-processor software and tailored for massively parallel multiprocessor shared memory computational platforms will be used by industry and researchers to assist in reducing and/or eliminating the environmental and economic barriers which limit full consideration of coal, shale and biomass as energy sources, to retain energy security, and to remediate waste and ecological problems. TURBULENT WALL JET IN BLAST WAVE PRECURSOR
A. L. Kuhl Jan. 1993 38 p Presented at the 1993 National Symposium on Shock Waves, Sendai, Japan, 11-15 Jan. 1993
(Contract W-7405-eng-48)
(DE93-011955; UCRL-JC-112713; CONF-9301100-1) Avail: CASI HC A03/MF A01

Numerical simulations of the turbulent dusty flow induced by an explosion over a ground surface were performed with a second-order Godunov code. Adaptive Mesh Refinement was used to capture the convective mixing processes on the computational grid. The most prominent feature of the flow was a turbulent wall jet that was induced by the precursor shock refraction into a thermal layer on the surface. Dust lofting occurred because the rotational structures of the boundary layer entrained dust from the ground surface. Scaling methods were defined in order to evaluate the mean and r.m.s. profiles of the wall jet. The profiles were shown to be similar to the profiles calculated for self-similar wall jets propagating over dust layers, and agreed with experimental profiles of a dusty boundary layer behind a shock. The Convective Mixing Model described here can be applied to a wide spectrum of fluid-dynamic mixing problems. DOE

A GALILEAN AND TENSORIAL INVARIANT k-EPSILON MODEL FOR NEAR WALL TURBULENCE
Z. Yang and T. H. Shih Jul. 1993 12 p Presented at the 24th Fluid Dynamics Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA
(Contract NCC3-233; RTOP 505-62-21)
(NASA-TM-106263; AIAA Paper 93-3105; ICOMP-93-24; CMOTT-93-10; E-7990; NAS 1.15:106263) Avail: CASI HC A03/MF A01

A k-epsilon model is proposed for wall bounded turbulent flows. In this model, the eddy viscosity is characterized by a turbulent velocity scale and a turbulent time scale. The time scale is bounded from below by the Kolmogorov time scale. The dissipation rate equation is reformulated using this time scale and no singularity exists at the wall. A new parameter R = k/S(nu) is introduced to characterize the damping function in the eddy viscosity. This parameter is determined by local properties of both the mean and the turbulent flow fields and is free from any geometry parameter. The proposed model is then Galilean and tensorial invariant. The model constants used are the same as in the high Reynolds number Standard k-epsilon Model. Thus, the proposed model will also be suitable for flows far from the wall. Turbulent channel flows and turbulent boundary layer flows with and without pressure gradients are calculated. Comparisons with the data from direct numerical simulations and experiments show that the model predictions are excellent for turbulent channel flows and turbulent boundary layers with favorable pressure gradients, good for turbulent boundary layers with zero pressure gradients, and fair for turbulent boundary layer with adverse pressure gradients. HIGH ORDER ACCURATE SOLUTIONS OF VISCOUS PROBLEMS
M. Ehtesham Hayder and Eli Turkel (Tel-Aviv Univ., Israel.) Jul. 1993 13 p Presented at the 24th Fluid Dynamics Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA
(RTOP 505-62-21)
(NASA-TM-106267; AIAA Paper 93-3074; ICOMP-93-26; E-7994; NAS 1.15:106267) Avail: CASI HC A03/MF A01

We consider a fourth order extension to MacCormack's scheme. The original extension was fourth order only for the inviscid terms but was second order for the viscous terms. We show how to modify the viscous terms so that the scheme is uniformly fourth order in the spatial derivatives. Applications are given to some boundary layer flows. In addition, for applications to shear flows the effect of the outflow boundary conditions are very important. We compare the accuracy of several of these different boundary conditions for both boundary layer and shear flows. Stretching at the outflow usually increases the oscillations in the numerical solution but the addition of a filtered sponge layer (with or without stretching) reduces such oscillations. The oscillations are generated by insufficient resolution of the shear layer. When the shear layer is sufficiently resolved then oscillations are not generated and there is less of a need for a nonreflecting boundary condition. Author (revised)

A RESEARCH PROGRAM FOR IMPROVING HEAT TRANSFER PREDICTION FOR THE LAMINAR TO TURBULENT TRANSITION REGION OF TURBINE VANES/BLADES
Frederick F. Simon Aug. 1993 35 p Presented at the Workshop on End-State Boundary Layer Transition, Blue Mountain Lake, NY, 15-18 Aug. 1993; sponsored by Syracuse Univ.
(RTOP 505-62-52)
(NASA-TM-106278; E-8015; NAS 1.15:106278) Avail: CASI HC A03/MF A01

A program sponsored by NASA for the investigation of the heat transfer in the transition region of turbine vanes and blades with the objective of improving the capability for predicting heat transfer is described. The accurate prediction of gas-side heat transfer is important to the determination of turbine longevity, engine performance, and developmental costs. The need for accurate predictions will become greater as the operating temperatures and stage loading levels of advanced turbine engines increase. The present methods for predicting transition shear stress and heat transfer on turbine blades are based on incomplete knowledge and are largely empirical. To meet the objective of the NASA program, a team approach consisting of researchers from government, universities, a research institute, and a small business is presented. The research is divided into the areas of experiments, direct numerical simulations (DNS), and turbulence modeling. A summary of the results to date is given for the above research areas in a high-disturbance environment (bypass transition) with a discussion of the model development necessary for use in numerical codes. QUALITY FACTORS AND LOCAL ADAPTION (WITH APPLICATIONS IN EULERIAN HYDRODYNAMICS)
W. P. Crowley 17 Jun. 1992 9 p Presented at the 7th IMACS International Conference on Computer Methods for Partial Differential Equations, New Brunswick, NJ, 22-24 Jun. 1992
(Contract W-7405-eng-48)
(DE93-010502; UCRL-JC-110862; CONF-9206185-12) Avail: CASI HC A02/MF A01

Adapting the mesh to suit the solution is a technique commonly used for solving both ODE's and PDE's. For Lagrangian hydrodynamics, ALE and Free-Lagrange are examples of structured and unstructured adaptive methods. For Eulerian hydrodynamics the two basic approaches are the macro-unstructuring technique and the micro-unstructuring technique. Here, we will describe a new micro-unstructuring technique, LAM, (for Local Adaptive Mesh) as applied to Eulerian hydrodynamics. The LAM technique consists of two independent parts: (1) the time advance scheme is a variation on the artificial viscosity method; and (2) the adaption scheme uses a micro-unstructured mesh with quadrilateral mesh elements. The adaption scheme makes use of quality factors and the relation between these and truncation errors is discussed. The time advance scheme; the adaption strategy; and the effect of different adaption parameters on numerical solutions are described. DOE

CRESLAF. VERSION 4.0: A FORTRAN PROGRAM FOR MODELING LAMINAR, CHEMICALLY REACTING, BOUNDARY-LAYER FLOW IN CYLINDRICAL OR PLANAR CHANNELS
M. E. Coltrin, H. K. Moffat, R. J. Kee, and F. M. Rupley Apr. 1993 50 p
(Contract DE-AC04-76DP-00789)
(DE93-012835; SAND-93-0478) Avail: CASI HC A03/MF A01

CRESLAF is a Fortran program that predicts the velocity, temperature, and species profiles in two-dimensional (planar or axisymmetric) channels. The program accounts for finite-rate gas-phase and surface chemical kinetics and molecular transport. The model employs the boundary-layer approximations for the fluid-flow equations, coupled to gas-phase and surface species continuity equations. The program runs in conjunction with the Chemkin preprocessors for the gas-phase and surface chemical reaction mechanisms and the transport properties. This report presents the equations defining the model, the method of solution, the input parameters to the program, and a sample problem illustrating its use. Applications of CRESLAF include chemical vapor deposition (CVD) reactors, heterogeneous catalysis on reactor walls, and corrosion processes. DOE

MARANGONI INSTABILITY IN A LIQUID LAYER WITH TWO FREE SURFACES
Robert J. Deissler, Alxander Oron (Technion - Israel Inst. of Tech., Haifa.), and J. C. Duh (Sverdrup Technology, Inc., Brook Park, OH.) Jul. 1993 26 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106166; ICOMP-93-15; E-7862; NAS 1.15:106166) Avail: CASI HC A03/MF A01

The onset of the Marangoni instability in a liquid layer with two free nearly insulating surfaces heated from below is studied. Linear stability analysis yields a condition for the emergence of a longwave or a finite wavelength instability from the quiescent equilibrium state. Using the method of asymptotic expansions, a weakly nonlinear evolution equation describing the spatiotemporal behavior of the velocity and temperature fields at the onset of the longwave instability is derived. The latter is given by delta(M) = 24, delta(M) being the difference between the upper and the lower Marangoni numbers. It is shown that in some parametric range one convective cell forms across the layer, while in other parametric domains two convective cells emerge between the two free surfaces. Author (revised)

ON NONLINEAR TOLLMIEN-SCHLICHTING/VORTEX INTERACTION IN THREE-DIMENSIONAL BOUNDARY LAYERS
Dominic A. R. Davis and Frank T. Smith (University Coll., London, England.) May 1993 29 p
(Contract NCC3-233; RTOP 505-62-21)
(NASA-TM-106184; ICOMP-93-17; E-7889; NAS 1.15:106184) Avail: CASI HC A03/MF A01

The instability of an incompressible three-dimensional boundary layer (that is, one with cross-flow) is considered theoretically and computationally in the context of vortex/wave interactions. Specifically the work centers on two low amplitude, lower-branch Tollmien-Schlichting waves which mutually interact to induce a weak longitudinal vortex flow; the vortex motion, in turn, gives rise to significant wave-modulation via wall-shear forcing. The characteristic Reynolds number is taken as a large parameter and, as a consequence, the waves' and the vortex motion are governed primarily by triple-deck theory. The nonlinear interaction is captured by a viscous partial-differential system for the vortex coupled with a pair of amplitude equations for each wave pressure. Three distinct possibilities were found to emerge for the nonlinear behavior of the flow solution downstream - an algebraic finite-distance singularity, far downstream saturation or far-downstream wave-decay (leaving pure vortex flow) - depending on the input conditions, the wave angles, and the size of the cross-flow. SHEAR FLOW CONTROL OF GAS JETS IN LIQUIDS
T. G. Ogden, L. A. Parnell, E. W. Hendricks, and W. M. Schieber Mar. 1993 10 p
(AD-A264673) Avail: CASI HC A02/MF A01

Passive control of shear flow is used to control the rate of mixing and stability of submerged gaseous jets in liquids. The object is to evaluate the effectiveness of recently developed shear flow control techniques for application to gaseous jets injected into liquids and ultimately to apply these techniques to gaseous oxidants injected into liquid metal fuels. These control techniques have been initially tested in nonreacting gas/liquid systems. A large increase in the degree of mixing and jet stability occurs when non-axisymmetric nozzles are used as injectors relative to injection by axisymmetric Fanno tube type nozzles. Jet volume spreading rate is increased by a factor of 4. A characteristic instability (the 'reverse shock' or reverse flow effect) occurring in such two-phase systems is greatly reduced by passive control of the shear flow. A simple passive technique of controlling entrainment is described which is effective in eliminating the reverse flow effect. The relevance of these control techniques to liquid metal combustion is discussed. DTIC

VISCOUS ANALYSIS OF THREE-DIMENSIONAL ROTOR FLOWS USING A MULTIGRID METHOD
A. Arnone (Florence Univ., Italy.) Jul. 1993 36 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106266; ICOMP-93-25; E-7993; NAS 1.15:106266) Avail: CASI HC A03/MF A01

A three-dimensional code for rotating blade-row flow analysis was developed. The space discretization uses a cell-centered scheme with eigenvalues scaling for the artificial dissipation. The computational efficiency of a four-stage Runge-Kutta scheme is enhanced by using variable coefficients, implicit residual smoothing, and a full-multigrid method. An application is presented for the NASA rotor 67 transonic fan. Due to the blade stagger and twist, a zonal, non-periodic H-type grid is used to minimize the mesh skewness. The calculation is validated by comparing it with experiments in the range from the maximum flow rate to a near-stall condition. A detailed study of the flow structure near peak efficiency and near stall is presented by means of pressure distribution and particle traces inside boundary layers. Author (revised)

A FOUR-DIMENSIONAL, MESOSCALE, NON-GAUSSIAN MULTISPECTRAL SMOKE MODEL. PHASE 1: FEASIBILITY STUDY Final Report
R. J. Yamartino, D. G. Strimaitis, J. S. Scire, and E. M. Insley Dec. 1992 70 p
(Contract DAAD07-91-C-0133)
(AD-A264805; ARL-CR-15) Avail: CASI HC A04/MF A01

The feasibility of developing a four-dimensional, non-Gaussian mesoscale multispectral smoke model that could run on a personal computer is investigated. Several of the model components are formulated, coded, and tested. This included the main driver program for accessing and interpolating the mesoscale winds and generating particle trajectories, a sub-grid-scale velocity field generator based on the kinematic simulation approach, and a dry deposition model for particle deposition velocities. Current understanding of flow and turbulence modeling is reviewed and can be applied to developing appropriate kinematic simulation fields. Technical approaches to account for the height and particle size dependent probability of particle removal and to compute the point and path average particle concentrations are also presented. Conclusions and recommendations for future work are included. DTIC

SHEAR COAXIAL INJECTOR ATOMIZATION PHENOMENA FOR COMBUSTING AND NON-COMBUSTING CONDITIONS
S. Pal, M. D. Moser, H. M. Ryan, M. J. Foust, and R. J. Santoro 1992 39 p

(Contract NAS8-38862; NAGw-1356)
(NASA-CR-193339; NAS 1.26:193339) Avail: CASI HC A03/MF A01

Measurements of LOX drop size and velocity in a uni-element liquid propellant rocket chamber are presented. The use of the Phase Doppler Particle Analyzer in obtaining temporally-averaged probability density functions of drop size in a harsh rocket environment has been demonstrated. Complementary measurements of drop size/velocity for simulants under cold flow conditions are also presented. The drop size/velocity measurements made for combusting and cold flow conditions are compared, and the results indicate that there are significant differences in the two flowfields. Author

MASSIVELY PARALLEL HYDRODYNAMICS ON UNSTRUCTURED GRIDS
M. S. Sahota and H. E. Trease 1993 5 p Presented at the 1993 International Simulators Conference on High Performance Computing, Arlington, VA, 29 Mar. - 1 Apr. 1993
(Contract W-7405-eng-36)
(DE93-007325; LA-UR-93-435; CONF-930372-4) Avail: CASI HC A01/MF A01 (US Sales Only)

We investigate the feasibility of using massively parallel Single Instruction Multiple Data (SIMD) and Multiple Instruction Multiple Data (MIMD) computer architectures for explicit three-dimensional unstructured-grid finite-element Lagrange and finite-volume free-Lagrange hydrodynamics. We compare the Cray-YMP, Connection Machine 200 (CM-200), and CM-5 computational times required for the foregoing algorithms. Although we observe very large global communication penalty (approximately 40-95% depending upon the problem) on the CM for these algorithms, moderate to good speedups over a single-processor Cray-YMP are obtained. Also, when the FORTRAN 90 code written for the CM is ported back to the Cray, we observe approximately 30-40% speedups over the original vectorized Cray coding. To reduce the global communication cost, we investigate the possibility of using an automatic generalized domain decomposition technique for MIMD architectures (CM-5) currently under development at the Thinking Machines Corporation. ACCRETION DISK VISCOSITY AND INTERNAL WAVES IN DISKS Ph.D. Thesis
Min Huang 1992 185 p
Avail: Univ. Microfilms Order No. DA9309192

Recently, Vishniac, Jin and Diamond suggested that internal waves in accretion disks play a critical role in generating magnetic fields, and consequently are indirectly responsible for angular momentum transfer in thin, conducting, and non-self-gravitational disk systems. A project in which we will construct a quantitative model of the internal wave spectrum in accretion disks is started. It includes two aspects of work. The physical properties of the waves in a thin, non-self-gravitational, and non-magnetized accretion disk with realistic vertical structure is cataloged and examined. Besides the low frequency internal waves discovered by Vishniac and Diamond, it was found that sound waves with low frequency and low axisymmetry (with small absolute value of m) are capable of a driving dynamo because they are (1) well confined in a layer with thickness 2(absolute value of m)H where H is the disk scale height; (2) highly dispersive so they may survive the strong dissipation caused by the coherent nonlinear interaction their high frequency partners experience; and (3) elliptically polarized because they are confined in the z-direction. As a first step towards constructing a quantitative theory of this dynamo effect, a framework of calculating resonant nonlinear interaction among waves in disk is established. We are developing a numerical code which will compute the steady spectrum of the wave field in this framework. For simplicity, we only include the low frequency internal waves suggested by Vishniac and Diamond in the present stage. In the vicinity of the static state, the time step whose length is determined by the evolution of the modes with the largest amplitudes is too large for the modes with smaller amplitudes and overshooting occurs. Through nonlinear coupling, this overshooting is amplified and appears as a numerical instability affecting the evolution of the large amplitude modes. Shorter time steps may delay the appearance of the instability but not cure it. Additionally, shorter and shorter time steps make the computation more and more inefficient. Two ways to improve the codes are suggested. Dissert. Abstr.

MODELLING QUASI-TWO-DIMENSIONAL TURBULENT SHEAR FLOW Ph.D. Thesis
Sofia Babarutsi 1991 223 p
Avail: Univ. Microfilms Order No. DANN72131

A two-length-scale turbulence model is introduced for the computation of quasi-two-dimensional turbulent shear flow with two distinct length scales of motion. In the model, the turbulence motions of the two distinct length scales are computed separately. The small-scale turbulence is treated as a background component locally in equilibrium while the large-scale turbulence is simulated using a second order closure procedure. The development of the turbulent shear flows depends on the rate of energy transfer from the large-scale to the small scale turbulence. Two mechanisms are identified to have a significant effect on the rate of this energy transfer. On one hand, the rate is reduced due to the confinement of the large-scale turbulence to two dimensional motion, since the nonlinear energy cascade process is less efficient in two-dimensional turbulent motion. On the other hand, the rate is enhanced due to the work done by the large-scale turbulent motion against the friction forces. The energy transfer rate due to friction is derived in the model using a two-step averaging procedure, whereas the transfer rate due to nonlinear cascade process is determined using a model equation. The data from a number of experimental investigations of quasi-two-dimensional turbulent shear flows are analyzed. These data support the notion of the two-length-scale turbulence model, that (1) the maintenance of the turbulent motion depends on the transfer of energy from the large-scale turbulence to the small-scale turbulence, and (2) the transfer rate is subjected to confinement and friction influences as specified in the model. Numerical computations are conducted using the two-length-scale model and a single-length-scale model. The results are compared with the experimental data. The two-length-scale model is superior in performance compared with the single-length-scale model, particularly in the intermediate region of the flow where both length scales of the turbulent motion are equally important. Dissert. Abstr.

NUMERICAL SIMULATIONS OF THERMAL CONVECTION IN RAPIDLY ROTATING SPHERICAL FLUID SHELLS Ph.D. Thesis
Zi-Ping Sun 1992 286 p
Avail: Univ. Microfilms Order No. DA9310954

Numerical simulations of thermal convection in rapidly rotating spherical shells of Boussinesq fluid were carried out with a nonlinear, three-dimensional, time-dependent spectral-transform code. The basic state is hydrostatic, spherically symmetric, and independent of time. The numerical methods, the numerical stability, and the adequacy of the spatial resolution were examined by a benchmarking study. A sequence of bifurcations from the onset of a steadily propagating convective state, to a periodic state, to a quasi-periodic state and thence a chaotic state was found. Convective solutions at each stage along the route to chaos were studied. The emphases are on the three dimensional and time-dependent convective structures and associated mean zonal flow. The spherical shell is heated from both below and within. The boundaries are isothermal and stress-free. The consequences of imposing a spatially varying temperature anomaly on the upper surface of a spherical shell on thermal convection in the shell was also explored. The spherical shell is heated from below and cooled from above. The lower boundary is isothermal and both boundaries are rigid and impermeable. The results show that the patterns and amplitudes of the convective motions and associated mean zonal and meridional flows depend largely on the pattern and amplitude of the imposed thermal anomaly. The purpose is to illustrate the influence of thermal conditions in the lower mantle on motions in the Earth's liquid outer core. Finally, numerical

simulations at both high Taylor and Rayleigh numbers were carried out. The spherical shell is heated from below and cooled from above. The boundaries are isothermal and stress-free. Columnar rolls that are quasi-layered in cylindrical radius and associated banded mean zonal flow are obtained. The quasi-layered convective structure and the banded zonal wind are consequent upon both the high Taylor and Rayleigh numbers. The numerical results confirm the theory that cylindrically multilayered columnar thermal convection occurs in rapidly rotating systems and can result in a banded zonal surface flow thereby providing an explanation in principle for the remarkable bandings of Jupiter and Saturn.

TURBULENCE MODELING FOR THRUST REVERSER FLOW FIELD PREDICTION METHODS Final Report, 30 Apr. 1990 - 31 Dec. 1992
Robert E. Childs, Laura C. Rodman, and Peter Bradshaw Dec. 1992 70 p
(Contract F33615-90-C-3002)
(AD-A266139; NEAR-TR-457; WL-TR-92-3121) Avail: CASI HC A04/MF A01

The use of thrust reversing on aircraft operating in ground effect produces complex flow fields, for which conventional turbulence models are inadequate. The main objective of the work was to produce an improved turbulence model. The work included experimental measurements of an impinging jet inclined 45 degrees into the crossflow. Large eddy simulation (LES) was used to identify the dominant turbulent physics in these flows and to guide the development of an improved k-epsilon model for Reynolds-averaged calculations. Modifications to the k-epsilon model for the effects of streamline curvature and vortex stretching (lateral divergence) were used. Compared to the original k-epsilon model, the modified model reduced by as much as 70 percent the errors in predicting the ground vortex location.

THE PHYSICS OF PATTERN FORMATION OF LIQUID INTERFACES
1993 26 p
(Contract DE-FG02-84ER-45131)
(DE93-013333; DOE/ER-45131/T2) Avail: CASI HC A03/MF A01

Energy consumption in fabrication of materials for all applications is process dependent. Improvements in the ability to process materials are of great importance to the DOE mission. This project addresses basic science questions related to the processing of materials and is aimed at understanding growth of interfaces and evolution of patterns on interfaces, both macroscopic and microscopic. Three laboratory experiments are proposed: A study of the changes in patterns available to the growth of a macroscopic interface when that interface is grown over one of a variety of 'microscopic' lattices; a study of reversible aggregation of colloidal particles in a mixed solvent, and of the interactions and relaxations of both solvent and suspended particles when thermodynamic conditions are changed for a liquid matrix with suspended particles or fibres; and an investigation of the sedimentation of particles in a quasi-two-dimensional viscous fluid, with attention both to the dynamics of the flow and to the roughness of the resulting surface of settled particles.

GRID OPTIMIZATION AND MULTIGRID TECHNIQUES FOR FLUID FLOW AND TRANSPORT PROBLEMS Ph.D. Thesis
Anand L. Pardhanani 1992 215 p
Avail: Univ. Microfilms Order No. DA9309251

Special numerical techniques for the efficient and accurate solution of fluid flow and certain other transport processes are investigated. These include adaptive redistribution and optimization of computational grids, multigrid techniques for convection-diffusion problems, and multigrid time-marching methods for non-stationary and nonlinear problems. The grid optimization strategy is based on constructing and minimizing a mathematical objective function which defines the desired grid properties. For convection-diffusion problems, it is demonstrated that standard multigrid techniques fail when the coarse grids violate mesh-size restrictions. A variety of alternate multigrid strategies are explored, including artificial dissipation, fine grid pre-elimination, self-adjoint formulation, defect correction, and combination with grid redistribution. Multilevel techniques are also developed for time-dependent problems, including evolution problems with non-steady or transient solutions, and steady-state problems solved with artificial time-marching. Both explicit and implicit integration schemes are investigated, and it is shown that significant performance improvements can be gained with the use of multigrid. These techniques are implemented and tested on representative model problems as well as practical applications of current research interest. The grid investigations involve optimization in model problems, and in large-scale 3-D aircraft wing-body configurations. The multigrid applications range from model convection-diffusion problems, to time-dependent problems, to coupled nonlinear problems in two major application areas. The first application involves simulating spatio-temporal patterns in a coupled, nonlinear, reaction-diffusion problem that models the behavior of the Belousov-Zhabotinskii reaction. This multi-species reaction, which exhibits intricate patterns in laboratory experiments, has attracted considerable interest in the field of nonlinear dynamics. The numerical simulation of this problem is carried out using the above multigrid strategies, and it is shown that considerable speed up can be achieved. The other main application involves the simulation of submicron semiconductor devices using a new hydrodynamic transport model. This is a very complex application, and many of its modeling and simulation aspects remain a subject of ongoing research. The present work has yielded preliminary results, including significant performance gains for a representative MOSFET structure in 1-D. The software for these applications is optimized to yield high performance on vector supercomputers such as the Cray Y-MP. This is demonstrated, in particular, for the applications involving timestepping, where computational efficiency is of crucial importance.

SAUNA: A SYSTEM FOR GRID GENERATION AND FLOW SIMULATION USING HYBRID STRUCTURED/UNSTRUCTURED GRIDS
P. N. Childs, J. A. Shaw, A. J. Peace, and J. M. Georgala May 1992 9 p Presented at the First European Computational Fluid Dynamics Conference, Brussels, Belgium, 7-11 Sept. 1992 Original contains color illustrations
(Contract SLS41B/2437)
(ARA-Memo-370) Avail: CASI HC A02/MF A01

The development of a flow simulation facility for predicting the aerodynamics of complex configurations wherein the grid is composed of both structured and unstructured regions is described. Issues relating to the generation and analysis of such grids and to the accurate and efficient computation of both inviscid and viscous flows thereon are considered. Further the development of a comprehensive post-processing and visualization facility is explored. Techniques are illustrated throughout by application to realistic aircraft geometries.

Vortex-induced forces and the consequent vibration of long cylindrical structures are important for a large number of engineering applications; the complexity of the underlying physical mechanisms is such that this is one of the canonical problems of fluid mechanics. Vortex shedding force varies in frequency and magnitude along the length of the structure causing the response at any point to be amplitude-modulated in space and time. The focus is on the measurement, via forced-oscillation experiments, of the vortex-induced lift and drag forces acting on circular cylinders undergoing sinusoidal and amplitude-modulated oscillations. Basic concepts on vortex formation and vortex-induced vibrations, a review of the existing literature, and details of the experimental apparatus and data processing methods are presented. Stationary and sinusoidal oscillation tests are presented. Several novel properties are described, among them the role of the lift force phase angle in causing the amplitude-limited nature of VIV, and use of the lift force excitation region in contrast with the often-quoted but quite different lift force lock-in region. Next, a comprehensive data error analysis and a simple VIV prediction scheme are described. New data on amplitude-modulated oscillations are presented. The concept of control of the mean wake velocity profile via the control of the major vortical feature is explored with possible applications being the reduction of the in-line wake velocity and alteration of the wake signature. ANNUAL RESEARCH BRIEFS, 1992 Progress Reports
Debra Spinks, comp. Jan. 1993 449 p Sponsored in part by AFOSR and ONR
(Contract NCC2-460)
(NASA-CR-194389; NAS 1.26:194389) Avail: CASI HC A19/MF A04

This report contains the 1992 annual progress reports of the Research Fellows and students of the Center for Turbulence Research. Considerable effort was focused on the large eddy simulation technique for computing turbulent flows. This increased activity has been inspired by the recent predictive successes of the dynamic subgrid scale modeling procedure which was introduced during the 1990 Summer Program. Several Research Fellows and students are presently engaged in both the development of subgrid scale models and their applications to complex flows. The first group of papers in this report contain the findings of these studies. They are followed by reports grouped in the general areas of modeling, turbulence physics, and turbulent reacting flows. The last contribution in this report outlines the progress made on the development of the CTR post-processing facility. For individual titles, see N94-12285 through N94-12320.

A LOCAL DYNAMIC MODEL FOR LARGE EDDY SIMULATION
Sandip Ghosal, Thomas S. Lund, and Parviz Moin *In its* Annual Research Briefs, 1992 Jan. 1993 p 3-25 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The dynamic model is a method for computing the coefficient C in Smagorinsky's model for the subgrid-scale stress tensor as a function of position from the information already contained in the resolved velocity field rather than treating it as an adjustable parameter. A variational formulation of the dynamic model is described that removes the inconsistency associated with taking C out of the filtering operation. This model, however, is still unstable due to the negative eddy-viscosity. Next, three models are presented that are mathematically consistent as well as numerically stable. The first two are applicable to homogeneous flows and flows with at least one homogeneous direction, respectively, and are, in fact, a rigorous derivation of the ad hoc expressions used by previous authors. The third model in this set can be applied to arbitrary flows, and it is stable because the C it predicts is always positive. Finally, a model involving the subgrid-scale kinetic energy is presented which attempts to model backscatter. This last model has some desirable theoretical features. However, even though it gives results in LES that are qualitatively correct, it is outperformed by the simpler constrained variational models. It is suggested that one of the constrained variational models should be used for actual LES while theoretical investigation of the kinetic energy approach should be continued in an effort to improve its predictive power and to understand more about backscatter. Avail: CASI HC A03/MF A04

The objective of this work is to construct and evaluate subgrid-scale models that depend on both the strain rate and the vorticity. This will be accomplished by first assuming that the subgrid-scale stress is a function of the strain and rotation rate tensors. Extensions of the Caley-Hamilton theorem can then be used to write the assumed functional dependence explicitly in the form of a tensor polynomial involving products of the strain and rotation rates. Finally, use of this explicit expression as a subgrid-scale model will be evaluated using direct numerical simulation data for homogeneous, isotropic turbulence. Derived from text

LARGE EDDY SIMULATIONS OF TIME-DEPENDENT AND BUOYANCY-DRIVEN CHANNEL FLOWS
William H. Cabot *In its* Annual Research Briefs, 1992 Jan. 1993 p 45-60 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The primary goal of this work has been to assess the performance of the dynamic SGS model in the large eddy simulation (LES) of channel flows in a variety of situations, viz., in temporal development of channel flow turned by a transverse pressure gradient and especially in buoyancy-driven turbulent flows such as Rayleigh-Benard and internally heated channel convection. For buoyancy-driven flows, there are additional buoyant terms that are possible in the base models, and one objective has been to determine if the dynamic SGS model results are sensitive to such terms. The ultimate goal is to determine the minimal base model needed in the dynamic SGS model to provide accurate results in flows with more complicated physical features. In addition, a program of direct numerical simulation (DNS) of fully compressible channel convection has been undertaken to determine stratification and compressibility effects. These simulations are intended to provide a comparative base for performing the LES of compressible (or highly stratified, pseudo-compressible) convection at high Reynolds number in the future. A NORMAL STRESS SUBGRID-SCALE EDDY VISCOSITY MODEL IN LARGE EDDY SIMULATION
K. Horiuti (Tokyo Univ., Japan.), N. N. Mansour, and John J. Kim *In* Stanford Univ., Annual Research Briefs, 1992 Jan. 1993 p 61-71 Sponsored in part by Tokyo Univ. (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The Smagorinsky subgrid-scale eddy viscosity model (SGS-EVM) is commonly used in large eddy simulations (LES) to represent the effects of the unresolved scales on the resolved scales. This model is known to be limited because its constant must be optimized in different flows, and it must be modified with a damping function to account for near-wall effects. The recent dynamic model is designed to overcome these limitations but is compositionally intensive as compared to the traditional SGS-EVM. In a recent study using direct numerical simulation data, Horiuti has shown that these drawbacks are due mainly to the use of an improper velocity scale in the SGS-EVM. He also proposed the use of the subgrid-scale normal stress as a new velocity scale that was inspired by a high-order anisotropic representation model. The testing of Horiuti, however, was conducted using DNS data from a low Reynolds number channel flow simulation. It was felt that further testing at higher Reynolds numbers and also using different flows (other than wall-bounded shear flows) were necessary steps needed to establish the validity of the new model. This is the primary motivation of the present study. The objective is to test the new model using DNS databases of high Reynolds number channel and fully developed turbulent mixing layer flows. The use of both channel (wall-bounded) and mixing layer flows is important for the development of accurate LES models because these two flows encompass many characteristic features of complex turbulent flows. LARGE EDDY SIMULATION OF SHOCK TURBULENCE INTERACTION
Sangsan Lee *In its* Annual Research Briefs, 1992 Jan. 1993 p 73-84 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

A nonconservative formulation of the energy equation (solving for internal energy) was used to perform large eddy simulations of compressible turbulence in Moin et al. due to its simplicity in implementing SGS models compared to the conservative formulation (solving for total energy). In problems with shocks in the domain, however, the total energy formulation is preferred due to its conservative nature. A conservative set of equations for the LES were derived from the nonconservative equations derived by Moin et al. Performance of the conservative formulation was compared with the experiment on decaying grid-generated turbulence as well as with the filtered DNS field. Various shock-capturing schemes were tested, and an ENO shock-capturing scheme of Shu and Osher was chosen for the simulation of shock/turbulence interaction. The scheme was tested and validated against the data base generated by DNS of weak shock waves. The results obtained with the essentially nonoscillatory (ENO) scheme were within 5 percent from the DNS results, and used less than 25 percent of the CPU time used in the DNS. Derived from text

APPLICATION OF A DYNAMIC SUBGRID-SCALE MODEL TO TURBULENT RECIRCULATING FLOWS
Y. Zang, R. L. Street, and J. R. Koseff *In its* Annual Research Briefs, 1992 Jan. 1993 p 85-95 (For primary document see N94-12284 01-34)
(Grant NSF CTS-87-19509)
Avail: CASI HC A03/MF A04

The dynamic subgrid-scale model of Germano et al. is implemented in a finite volume formulation and applied to the simulation of turbulent flow in a three-dimensional lid-driven cavity at Reynolds number of 7500. The filtering operation is carried out in physical space, and the model coefficient is calculated locally. The computed mean and rms velocities as well as the Reynolds stress are compared with experimental data. It is shown that backscatter from small to large scales is necessary to sustain turbulent fluctuations. The model is being applied to the simulation of turbulent flows in a stratified and rotating environment in complex geometries. Derived from text

LARGE-EDDY SIMULATION OF TURBULENT FLOW WITH A SURFACE-MOUNTED TWO-DIMENSIONAL OBSTACLE
Kyung-Soo Yang and Joel H. Ferziger *In its* Annual Research Briefs, 1992 Jan. 1993 p 97-111 (For primary document see N94-12284 01-34)
(Contract N00014-89-J-1343)
Avail: CASI HC A03/MF A04

In this paper, we perform a large eddy simulation (LES) of turbulent flow in a channel containing a two-dimensional obstacle on one wall using a dynamic subgrid-scale model (DSGSM) at Re = 3210, based on bulk velocity above the obstacle and obstacle height; the wall layers are fully resolved. The low Re enables us to perform a DNS (Case 1) against which to validate the LES results. The LES with the DSGSM is designated Case 2. In addition, an LES with the conventional fixed model constant (Case 3) is conducted to allow identification of improvements due to the DSGSM. We also include LES at Re = 82,000 (Case 4) using conventional Smagorinsky subgrid-scale model and a wall-layer model. The results will be compared with the experiment of Dimaczek et al. SIMILARITY STATES OF HOMOGENEOUS STABLY-STRATIFIED TURBULENCE AT INFINITE FROUDE NUMBER
Jeffrey R. Chasnov *In its* Annual Research Briefs, 1992 Jan. 1993 p 113-127 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

We present evidence of similarity states which may develop inhomogeneous stably-stratified flows if a dimensionless group in addition to the Reynolds number, the so-called Froude number, is sufficiently large. Here, we define the Froude number as the ratio of the internal wave time-scale to the turbulence time-scale. We examine three different similarity states which may develop depending on the initial conditions of the velocity and density fields. Theoretical arguments and results of large-eddy simulations will be presented. We will conclude this report with some speculative thoughts on similarity states which may develop in stably-stratified turbulence at arbitrary Froude number as well as our future research plans in this area. When analyzing many turbulent flows, the effects of compressibility can be neglected. Even some relatively high-speed flows, such as boundary layers generated by a supersonic aircraft, produce turbulent statistics that are similar to those found for the incompressible case. There are other situations, however, in which the non-zero divergence of the turbulence leads to behavior that is fundamentally different from that found at constant density. Examples include flows created by internal combustion engines, hypersonic flight, and supersonic combustion. It is with instances such as these that this project is concerned. In particular, we are interested in the effects of compressibility on turbulence near a smooth solid constant temperature surface; our primary objective is an increased physical understanding that can be used to improve turbulence models of wall-bounded compressible flows. With this in mind, we have begun a direct numerical simulation (DNS) study of turbulence in a plane channel. Because all of the relevant spatial and temporal scales are to be resolved, the simulations require no subgrid scale parameterization. The DNS code developed by Buell to study compressible plane Couette flow was modified to solve the compressible Navier-Stokes equations in the plane channel. The channel was chosen over the Couette flow for two reasons: (1) to avoid using the very large streamwise domains needed to adequately capture the large Couette vortical structures; and (2) to make use of previous experience by considering the compressible version of a well established case and isolate finite Mach number effects by comparing to the incompressible channel. DIRECT NUMERICAL SIMULATION OF HOT JETS
Marc C. Jacob *In its* Annual Research Briefs, 1992 Jan. 1993 p 145-160 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The ultimate motivation of this work is to investigate the stability of two dimensional heated jets and its implications for aerodynamic sound generation from data obtained with direct numerical simulations (DNS). As pointed out in our last report, these flows undergo two types of instabilities, convective or absolute, depending on their temperature. We also described the limits of earlier experimental and theoretical studies and explained why a numerical investigation could give us new insight into the physics of these instabilities. The aeroacoustical interest of these flows was also underlined. In order to reach this goal, we first need to succeed in the DNS of heated jets. Our past efforts have been focused on this issue which encountered several difficulties. Our numerical difficulties are directly related to the physical problem we want to investigate since these absolutely or almost absolutely unstable flows are by definition very sensitive to the smallest disturbances and are very likely to reach nonlinear saturation through a numerical feedback mechanism. As a result, it is very difficult to compute a steady laminar solution using a spatial DNS. A steady state was reached only for strongly co-flowed jets, but these flows are almost equivalent to two independent mixing layers. Thus they are far from absolute instability and have much lower growth rates. Author (revised)

NUMERICAL SIMULATION USING VORTICITY-VECTOR POTENTIAL FORMULATION

Hiroshi Tokunaga *In its* Annual Research Briefs, 1992 Jan. 1993 p 175-184 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

An accurate and efficient computational method is needed for three-dimensional incompressible viscous flows in engineering applications. On solving the turbulent shear flows directly or using the subgrid scale model, it is indispensable to resolve the small scale fluid motions as well as the large scale motions. From this point of view, the pseudo-spectral method is used so far as the computational method. However, the finite difference or the finite element methods are widely applied for computing the flow with practical importance since these methods are easily applied to the flows with complex geometric configurations. However, there exist several problems in applying the finite difference method to direct and large eddy simulations. Accuracy is one of most important problems. This point was already addressed by the present author on the direct simulations on the instability of the plane Poiseuille flow and also on the transition to turbulence. In order to obtain high efficiency, the multi-grid Poisson solver is combined with the higher-order, accurate finite difference method. The formulation method is also one of the most important problems in applying the finite difference method to the incompressible turbulent flows. The three-dimensional Navier-Stokes equations have been solved so far in the primitive variables formulation. One of the major difficulties of this method is the rigorous satisfaction of the equation of continuity. In general, the staggered grid is used for the satisfaction of the solenoidal condition for the velocity field at the wall boundary. However, the velocity field satisfies the equation of continuity automatically in the vorticity-vector potential formulation. From this point of view, the vorticity-vector potential method was extended to the generalized coordinate system. In the present article, we adopt the vorticity-vector potential formulation, the generalized coordinate system, and the 4th-order accurate difference method as the computational method. We present the computational method and apply the present method to computations of flows in a square cavity at large Reynolds number in order to investigate its effectiveness. Author (revised)

REYNOLDS STRESS CLOSURE MODELING IN WALL-BOUNDED FLOWS

Paul A. Durbin *In its* Annual Research Briefs, 1992 Jan. 1993 p 185-197 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

This report describes two projects. Firstly, a Reynolds stress closure for near-wall turbulence is described. It was motivated by the simpler k-epsilon-(v-bar(exp 2)) model described in last year's annual research brief. Direct Numerical Simulation of three-dimensional channel flow shows a curious decrease of the turbulent kinetic energy. The second topic of this report is a model which reproduces this effect. That model is described and used to discuss the relevance of the three dimensional channel flow simulation to swept wing boundary layers. Author (revised)

APPLICATION OF A REYNOLDS STRESS MODEL TO SEPARATING BOUNDARY LAYERS

Sung Ho Ko *In its* Annual Research Briefs, 1992 Jan. 1993 p 199-211 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

Separating turbulent boundary layers occur in many practical engineering applications. Nonetheless, the physics of separation/reattachment of flows is poorly understood. During the past decade, various turbulence models were proposed and their ability to successfully predict some types of flows was shown. However. prediction of separating/reattaching flows is still a formidable task for model developers. The present study is concerned with the process of separation from a smooth surface. Features of turbulent separating boundary layers that are relevant to modeling include the following: the occurrence of zero wall shear stress, which causes breakdown of the boundary layer approximation; the law of the wall not being satisfied in the mean back flow region; high turbulence levels in the separated region; a significant low-frequency motion in the separation bubble; and the turbulence structure of the separated shear layer being quite different from that of either the mixing layers or the boundary layers. These special characteristics of separating boundary layers make it difficult for simple turbulence models to correctly predict their behavior. Author (revised)

PROGRESS IN MODELING HYPERSONIC TURBULENT BOUNDARY LAYERS

Otto Zeman *In its* Annual Research Briefs, 1992 Jan. 1993 p 213-225 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

A good knowledge of the turbulence structure, wall heat transfer, and friction in turbulent boundary layers (TBL) at high speeds is required for the design of hypersonic air breathing airplanes and reentry space vehicles. This work reports on recent progress in the modeling of high speed TBL flows. The specific research goal described here is the development of a second order closure model for zero pressure gradient TBL's for the range of Mach numbers up to hypersonic speeds with arbitrary wall cooling requirements. RECEPTIVITY IN PARALLEL FLOWS: AN ADJOINT APPROACH

D. Christopher Hill *In its* Annual Research Briefs, 1992 Jan. 1993 p 227-236 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

Linear receptivity studies in parallel flows are aimed at understanding how external forcing couples to the natural unstable motions which a flow can support. The vibrating ribbon problem models the original Schubauer and Skramstad boundary layer experiment and represents the classic boundary layer receptivity problem. The process by which disturbances are initiated in convectively-unstable jets and shear layers has also received attention. Gaster was the first to handle the boundary layer analysis with the recognition that spatial modes, rather than temporal modes, were relevant when studying convectively-unstable flows that are driven by a time-harmonic source. The amplitude of the least stable spatial mode, far downstream of the source, is related to the source strength by a coupling coefficient. The determination of this coefficient is at the heart of this type of linear receptivity study. The first objective of the present study was to determine whether the various wave number derivative factors, appearing in the coupling coefficients for linear receptivity problems, could be reexpressed in a simpler form involving adjoint eigensolutions. Secondly, it was hoped that the general nature of this simplification could be shown; indeed, a rather elegant characterization of the receptivity properties of spatial instabilities does emerge. The analysis is quite distinct from the usual Fourier-inversion procedures, although a detailed knowledge of the spectrum of the Orr-Sommerfeld equation is still required. Since the cylinder wake analysis proved very useful in addressing control considerations, the final objective was to provide a foundation upon which boundary layer control theory may be developed. LOCAL ISOTROPY IN HIGH REYNOLDS NUMBER TURBULENT SHEAR FLOWS

Seyed G. Saddoughi *In its* Annual Research Briefs, 1992 Jan. 1993 p 237-262 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

This is a report on the continuation of experiments, which Dr. Srinivas Veeravalli and the present author started in 1991, to investigate the hypothesis of local isotropy in shear flows. This hypothesis, which states that at sufficiently high Reynolds numbers the small-scale structures of turbulent motions are independent of large-scale structures and mean deformations, has been used in theoretical studies of turbulence and computational methods like large-eddy simulation. The importance of Kolmogorov's ideas arises from the fact that they create a foundation for turbulence theory. Author (revised)

The assumption that turbulence at large wave-numbers is isotropic and has universal spectral characteristics which are independent of the flow geometry, at least for high Reynolds numbers, has been a cornerstone of closure theories as well as of the most promising recent development in the effort to predict turbulent flows, viz. large eddy simulations. This hypothesis was first advanced by Kolmogorov based on the supposition that turbulent kinetic energy cascades down the scales (up the wave-numbers) of turbulence and that, if the number of these cascade steps is sufficiently large (i.e. the wave-number range is large), then the effects of anisotropies at the large scales are lost in the energy transfer process. Experimental attempts were repeatedly made to verify this fundamental assumption. However, Van Atta has recently suggested that an examination of the scalar and velocity gradient fields is necessary to definitively verify this hypothesis or prove it to be unfounded. Of course, this must be carried out in a flow with a sufficiently high Reynolds number to provide the necessary separation of scales in order unambiguously to provide the possibility of local isotropy at large wave-numbers. An opportunity to use our 12-sensor hot-wire probe to address this issue directly was made available at the 80'x120' wind tunnel at the NASA Ames Research Center, which is normally used for full-scale aircraft tests. An initial report on this high Reynolds number experiment and progress toward its evaluation is presented. Author (revised)

PROBABILITY DENSITY DISTRIBUTION OF VELOCITY DIFFERENCES AT HIGH REYNOLDS NUMBERS

Alexander A. Praskovsky (Tsentralni Aerogidrodinamicheskii Inst., Moscow, USSR.) *In its* Annual Research Briefs, 1992 Jan. 1993 p 269-276 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

Recent understanding of fine-scale turbulence structure in high Reynolds number flows is mostly based on Kolmogorov's original and revised models. The main finding of these models is that intrinsic characteristics of fine-scale fluctuations are universal ones at high Reynolds numbers, i.e., the functional behavior of any small-scale parameter is the same in all flows if the Reynolds number is high enough. The only large-scale quantity that directly affects small-scale fluctuations is the energy flux through a cascade. In dynamical equilibrium between large- and small-scale motions, this flux is equal to the mean rate of energy dissipation epsilon. The pdd of velocity difference is a very important characteristic for both the basic understanding of fully developed turbulence and engineering problems. Hence, it is important to test the findings: (1) the functional behavior of the tails of the probability density distribution (pdd) represented by P(delta(u)) is proportional to exp(-b(r) absolute value of delta(u)/sigma(sub delta(u))) and (2) the logarithmic decrement b(r) scales as b(r) is proportional to r(sup 0.15) when separation r lies in the inertial subrange in high Reynolds number laboratory shear flows. THE IDEAL KOLMOGOROV INERTIAL RANGE AND CONSTANT

Ye Zhou *In its* Annual Research Briefs, 1992 Jan. 1993 p 277-283 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

The energy transfer statistics measured in numerically simulated flows are found to be nearly self-similar for wavenumbers in the inertial range. Using the measured self-similar form, an 'ideal' energy transfer function and the corresponding energy flux rate were deduced. From this flux rate, the Kolmogorov constant was calculated to be 1.5, in excellent agreement with experiments. Author (revised)

THE HELICAL DECOMPOSITION AND THE INSTABILITY ASSUMPTION

Fabian A. Waleffe *In its* Annual Research Briefs, 1992 Jan. 1993 p 285-289 (For primary document see N94-12284 01-34)
Avail: CASI HC A01/MF A04

Direct numerical simulations show that the triadic transfer function T(k,p,q) peaks sharply when q (or p) is much smaller than k. The triadic transfer function T(k,p,q) gives the rate of energy input into wave number k from all interactions with modes of wave number p and q, where k, p, q form a triangle. This observation was thought to suggest that energy is cascaded downscale through non-local interactions with local transfer and that there was a strong connection between large and small scales. Both suggestions were in contradiction with the classical Kolmogorov picture of the energy cascade. The helical decomposition was found useful in distinguishing between kinematically independent interactions. That analysis has gone beyond the question of non-local interaction with local transfer. In particular, an assumption about the statistical direction of triadic energy transfer in any kinematically independent interaction was introduced (the instability assumption). That assumption is not necessary for the conclusions about non-local interactions with local transfer recalled above. In the case of turbulence under rapid rotation, the instability assumption leads to the prediction that energy is transferred in spectral space from the poles of the rotation axis toward the equator. The instability assumption is thought to be of general validity for any type of triad interactions (e.g. internal waves). The helical decomposition and the instability assumption offer detailed information about the homogeneous statistical dynamics of the Navier-Stokes equations. The objective was to explore the validity of the instability assumption and to study the contributions of the various types of helical interactions to the energy cascade and the subgrid-scale eddy-viscosity. This was done in the context of spectral closures of the Direct Interaction or Quasi-Normal type. Author (revised)

SUPERFLUID TURBULENCE

David C. Samuels *In its* Annual Research Briefs, 1992 Jan. 1993 p 291-301 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

At low temperatures (below 5 Kelvin), helium is a liquid with a very low kinematic viscosity. It was proposed that wind tunnels could be built using liquid helium as the test fluid. The primary advantages of such wind tunnels would be a combination of large Reynolds numbers and a relatively small apparatus. It is hoped that this combination will allow the study of high Reynolds number flows in an academic setting. There are two basic types of liquid helium wind tunnels that can be built, corresponding to the two phases of liquid helium. The high temperature phase (between approximately 2 to 5 Kelvin) is called helium 1 and is a Navier-Stokes fluid. There are no unanswered scientific questions about the design or operation of a wind tunnel in the helium 1 phase. The low temperature phase (below approximately 2 Kelvin) of liquid helium is called helium 2. This is a quantum fluid, meaning that there are some properties of helium 2 which are directly due to quantum mechanical effects and which are not observed in Navier-Stokes fluids. The quantum effects that are relevant to this paper are: (1) helium 2 is well described as a superposition of two separate fluids called the superfluid and the normal fluid. The normal-fluid component is a Navier-Stokes fluid and the superfluid is an irrotational Euler fluid; and (2) circulation in the superfluid exists only in quantized vortex filaments. All quantized vortex filaments have identical circulations kappa and core size a. The objective of the research at CTR was to develop an understanding of the microscopic processes responsible for the observed Navier-Stokes behavior of helium 2 flows. Author (revised)

REGENERATION OF NEAR-WALL TURBULENCE STRUCTURES

James M. Hamilton, John J. Kim, and Fabian A. Waleffe *In its* Annual Research Briefs, 1992 Jan. 1993 p 303-315 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

An examination of the regeneration mechanisms of near-wall turbulence and an attempt to investigate the critical Reynolds number conjecture of Waleffe & Kim is presented. The basis is an extension of the 'minimal channel' approach of Jimenez and Moin which emphasizes the near-wall region and further reduces the complexity of the turbulent flow. Reduction of the flow Reynolds number to the minimum value which will allow turbulence to be sustained has the effect of reducing the ratio of the largest scales to the smallest scales or, equivalently, of causing the near-wall region to fill more of the area between the channel walls. In addition, since each wall may have an active near-wall region, half of the channel is always somewhat redundant. If a plane Couette flow is instead chosen as the base flow, this redundancy is eliminated: the mean shear of a plane Couette flow has a single sign, and at low Reynolds numbers, the two wall regions share a single set of structures. A minimal flow with these modifications possesses, by construction, the strongest constraints which allow sustained turbulence, producing a greatly simplified flow in which the regeneration process can be examined. Author (revised)

EXPERIMENTS ON NEAR-WALL STRUCTURE OF THREE-DIMENSIONAL BOUNDARY LAYERS
Karen A. Flack and J. P. Johnston *In its* Annual Research Briefs, 1992 Jan. 1993 p 317-324 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

Investigations of three-dimensional turbulent boundary layers have shown basic differences between two- and three-dimensional flows. These differences can significantly impact the modeling of three-dimensional flows since many flow models are based on results from two-dimensional boundary layers. In many cases the shear stress vector direction has been shown to lag relative to the direction of the mean velocity gradient as the cross flow grows downstream. Coincidence of these vectors is necessary for a scalar eddy viscosity modeling assumption. A second effect is a reduction in magnitude of the shear stress and/or the shear stress to turbulence energy ratio, a(sub 1). This reduction has been observed in several experiments. Recent numerical simulations also indicate wall-layer structural differences between two- and three-dimensional boundary layers. The differences in structure between two- and three-dimensional boundary layers was also addressed in the experiment of Littell & Eaton. The experiment used two-point correlations to investigate the vortical structures in a three dimensional boundary layer on a spinning disk. It was found that each sign of longitudinal vortex is equally likely to exist, but one sign of vorticity is associated with a structure which is better at producing ejections. The goal of the current investigation is to study the structure of the inner layers. Among other questions, the differences between the effects deduced from the three-dimensional flow simulations and the effects seen in experiments can be examined. The research concentrates on the structure of the wall-layer through flow visualization and direct turbulence measurements down to y(+) = 5. Author (revised)

THE THREE-DIMENSIONAL EVOLUTION OF A PLANE WAKE
H. Maekawa (University of Electro-Communications, Chofu, Japan.), R. D. Moser, and N. N. Mansour *In* Stanford Univ., Annual Research Briefs, 1992 Jan. 1993 p 325-334 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

In the past three decades, linear stability analysis has led to a comprehensive understanding of the linear stages of transition in plane wakes. Our understanding of the nonlinear and turbulent stages is less developed. Nonlinear theory developed by Papageorgiou and Smith was used to study the long-wavelength regime in wakes. The nonlinear and turbulent stages were investigated experimentally, and few numerical studies examined the early nonlinear stages of forced wakes. The evolution of three dimensional disturbances in an incompressible wake is investigated using direct numerical simulations. The instantaneous three-dimaensional structures and corresponding statistics are presented. Author (revised)

MIXING IN A STRATIFIED SHEAR FLOW: ENERGETICS AND SAMPLING
G. N. Ivey (University of Western Australia, Nedlands.), J. R. Koseff, D. A. Briggs, and J. H. Ferziger *In its* Annual Research Briefs, 1992 Jan. 1993 p 335-344 (For primary document see N94-12284 01-34)
(Contract N00014-92-J-1611)
Avail: CASI HC A02/MF A04

Direct numerical simulations of the time evolution of homogeneous stably stratified shear flows have been performed for Richardson numbers from 0 to 1 and for Prandtl numbers between 0.1 and 2. The results indicate that mixing efficiency R(sub f) varies with turbulent Froude number in a manner consistent with laboratory experiments performed with Prandtl numbers of 0.7 and 700. However, unlike the laboratory results, for a particular Froude number, the simulations do not show a clear dependence on the magnitude of R(sub f) on Pr. The observed maximum value of R(sub f) is 0.25. When averaged over vertical length scales of an order of magnitude greater than either the overturning or Ozmidov scales of the flow, the simulations indicate that the dissipation rate epsilon is only weakly lognormally distributed with an intermittency of about 0.01 whereas estimated values in the ocean are 3 to 7. LIF MEASUREMENTS OF SCALAR MIXING IN TURBULENT SHEAR LAYERS
Paris S. Karasso and M. G. Mungal *In its* Annual Research Briefs, 1992 Jan. 1993 p 345-356 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The structure of shear layer flows at high Reynolds numbers remains a very interesting problem. Straight mixing layers have been studied and yielded information on the probability density function (pdf) of a passive scalar across the layer. Konrad and Koochesfahani & Dimotakis measured the pdf of the mixture fraction for mixing layers of moderate Reynolds numbers, each about 25,000 (Re based on velocity difference and visual thickness). Their measurements showed a 'non-marching' pdf (central hump which is invariant from edge to edge across the layer), a result which is linked to the visualizations of the spanwise Kelvin-Helmholtz (K-H) instability mode, which is the primary instability for plane shear layer flows. A secondary instability mode, the Taylor-Gortler (T-G) instability, which is associated with streamwise vortical structures, has also been observed in shear layers. Image reconstruction by Jimenez et al. and volume renderings by Karasso & Mungal at low Re numbers have demonstrated that the K-H and the T-G instability modes occur simultaneously in a non-mutually destructive way, evidence that supports the quasi two-dimensional aspect of these flows and the non-marching character of the pdf at low Reynolds numbers. At higher Re numbers though, the interaction of these two instability modes is still unclear and may affect the mixing process. In this study, we perform measurements of the concentration pdf of plane mixing layers for different operating conditions. At a speed ratio of r = U(sub 1)/U(sub 2) = 4:1, we examine three Reynolds number cases: Re = 14,000, Re = 31,000, and Re = 62,000. Some other Re number cases' results, not presented in detail, are invoked to explain the behavior of the pdf of the concentration field. A case of r = 2.6:1 at Re = 20,000 is also considered. The planar laser-induced fluorescence technique is used to yield quantitative measurements. The different Re are obtained by changing the velocity magnitudes of the two streams. The question of resolution of these measurements is addressed. In order to investigate the effects of the initial conditions on the development and the structure of the mixing layer, the boundary layer on the high-speed side of the splitter plate is tripped. The average concentration and the average mixed fluid concentration are also calculated to further understand the changes in the shear layer for the different cases examined. Derived from text

PLANE MIXING LAYER VORTICAL STRUCTURE KINEMATICS
Richard L. LeBoeuf *In its* Annual Research Briefs, 1992 Jan. 1993 p 357-371 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The objective of the current project was to experimentally investigate the structure and dynamics of the streamwise vorticity in a plane mixing layer. The first part of this research program was intended to clarify whether the observed decrease in mean streamwise vorticity in the far-field of mixing layers is due primarily to the 'smearing' caused by vortex meander or to diffusion. Two-point velocity correlation measurements have been used to show that there is little spanwise meander of the large-scale streamwise vortical structure. The correlation measurements also indicate a large degree of transverse meander of the streamwise vorticity which is not surprising since the streamwise vorticity exists in the inclined braid region between the spanwise vortex core regions. The streamwise convection of the braid region thereby introduces an apparent transverse meander into measurements using stationary probes. These results corroborated with estimated secondary velocity profiles in which the streamwise vorticity produces a signature which was tracked in time. Derived from text

NUMERICAL SIMULATION OF THE NON-NEWTONIAN MIXING LAYER
Jalel Azaiez and G. M. Homsy *In its* Annual Research Briefs, 1992 Jan. 1993 p 373-380 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

This work is a continuing effort to advance our understanding of the effects of polymer additives on the structures of the mixing layer. In anticipation of full nonlinear simulations of the non-Newtonian mixing layer, we examined in a first stage the linear stability of the non-Newtonian mixing layer. The results of this study show that, for a fluid described by the Oldroyd-B model, viscoelasticity reduces the instability of the inviscid mixing layer in a special limit where the ratio (We/Re) is of order 1 where We is the Weissenberg number, a measure of the elasticity of the flow, and Re is the Reynolds number. In the present study, we pursue this project with numerical simulations of the non-Newtonian mixing layer. Our primary objective is to determine the effects of viscoelasticity on the roll-up structure. We also examine the origin of the numerical instabilities usually encountered in the simulations of non-Newtonian fluids. Derived from text

PDF APPROACH FOR TURBULENT SCALAR FIELD: SOME RECENT DEVELOPMENTS
Feng Gao *In its* Annual Research Briefs, 1992 Jan. 1993 p 381-391 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The probability density function (PDF) method has been proven a very useful approach in turbulence research. It has been particularly effective in simulating turbulent reacting flows and in studying some detailed statistical properties generated by a turbulent field There are, however, some important questions that have yet to be answered in PDF studies. Our efforts in the past year have been focused on two areas. First, a simple mixing model suitable for Monte Carlo simulations has been developed based on the mapping closure. Secondly, the mechanism of turbulent transport has been analyzed in order to understand the recently observed abnormal PDF's of turbulent temperature fields generated by linear heat sources. THE EVOLUTION EQUATION FOR THE FLAME SURFACE DENSITY IN TURBULENT PREMIXED COMBUSTION c25
Arnaud Trouve *In its* Annual Research Briefs, 1992 Jan. 1993 p 393-409 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The mean reaction rate in flamelet models for turbulent premixed combustion depends on two basic quantities: a mean chemical rate, called the flamelet speed, and the flame surface density. Our previous work had been primarily focused on the problem of the structure and topology of turbulent premixed flames, and it was then determined that the flamelet speed, when space-averaged, is only weakly sensitive to the turbulent flow field. Consequently, the flame surface density is the key quantity that conveys most of the effects of the turbulence on the rate of energy release. In flamelet models, this quantity is obtained via a modeled transport equation called the Sigma-equation. Past theoretical work has produced a rigorous approach that leads to an exact but unclosed formulation for the turbulent Sigma-equation. In the exact Sigma-equation, it appears that the dynamical properties of the flame surface density are determined by a single parameter, namely the turbulent flame stretch. Unfortunately, the turbulent flame stretch as well as the flame surface density is not available from experiments, and, in the absence of experimental data, little is known on the validity of the closure assumptions used in current flamelet models. Direct Numerical Simulation (DNS) is the alternative approach to get basic information on these fundamental quantities. In the present work, three-dimensional DNS of premixed flames in isotropic turbulent flow is used to estimate the different terms appearing in the Sigma-equation. A new methodology is proposed to provide the source and sink terms for the flame surface density, resolved both temporally and spatially throughout the turbulent flame brush. Using this methodology, our objective is to extract the turbulent flame stretch from the DNS data base and then perform extensive comparisons with flamelet models. Thanks to the detailed information produced by the DNS-based analysis, it is expected that this type of comparison will not only underscore the shortcomings of current models, but also suggest ways to improve them. STUDY AND MODELING OF FINITE RATE CHEMISTRY EFFECTS IN TURBULENT NON-PREMIXED FLAMES c25
Luc Vervisch *In its* Annual Research Briefs, 1992 Jan. 1993 p 411-429 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

The development of numerical models that reflect some of the most important features of turbulent reacting flows requires information about the behavior of key quantities in well defined combustion regimes. In turbulent flames, the coupling between turbulent and chemical processes is so strong that it is extremely difficult to isolate the role played by one individual physical phenomenon. Direct numerical simulation (hereafter DNS) allows us to study in detail the turbulence-chemistry interaction in some restricted but completely defined situations. Globally, non-premixed flames are controlled by two limiting regimes: the fast chemistry case, where the turbulent flame can be pictured as a random distribution of local chemical equilibrium problems; and the slow chemistry case, where the chemistry integrates in time the turbulent fluctuations. The Damkoehler number, ratio of a mechanical time scale to chemical time scale, is used to distinguish between these regimes. Today most of the industrial computer codes are able to perform predictions in the hypothesis of local equilibrium chemistry using a presumed shape for the probability density function (pdt) of the conserved scalar. However, the finite rate chemistry situation is of great interest because industrial burners usually generate regimes in which, at some points, the flame is undergoing local extinction or at least non-equilibrium situations. Moreover, this variety of situations strongly influences the production of pollutants. To quantify finite rate chemistry effect, the interaction between a non-premixed flame and a free decaying turbulence is studied using DNS. The attention is focused on the dynamic of extinction, and an attempt is made to quantify the effect of the reaction on the small scale mixing process. The unequal diffusivity effect is also addressed. Finally, a simple turbulent combustion model based on the DNS observations and tractable in real flow configurations is proposed. Derived from text

WHY DOES PREFERENTIAL DIFFUSION STRONGLY AFFECT PREMIXED TURBULENT COMBUSTION? c25
Vadim R. Kuznetsov (Izdatelstvo Nauka, Moscow, USSR.) *In its* Annual Research Briefs, 1992 Jan. 1993 p 443-453 (For primary document see N94-12284 01-34)
Avail: CASI HC A03/MF A04

Combustion of premixed reactants in a turbulent flow is a classical but unresolved problem. The key problem is to explain the following data: the maximal turbulent and laminar burning velocities u(sub t) and u(sub L) occur at different equivalence ratios Phi. It is known that the equivalence ratio varies along a curved flame if molecular diffusivity D(sub fuel) does not equal D(sub oxygen). However, the mean flame radius of curvature is much larger than the laminar flame thickness delta-L. Therefore, significant influence of preferential diffusion should occur only if the flame propagation speed varies with flame curvature. This conclusion agrees with Zel'dovich's long-standing idea about the important role of leading points of a flame. The main objective of this paper is to prove Zel'dovich's hypothesis. An equation for the mean flame surface area density (MFSAD) is employed for this purpose. The second objective of this paper is to suggest a different approach to the derivation of the equation for MFSAD. It is based on the pdf equation for the reaction progress variable C and the relation between the pdf and MFSAD. This treatment suggests an entirely different closure assumption. Derived from text

TENSORAL: A SYSTEM FOR POST-PROCESSING TURBULENCE SIMULATION DATA c24
Eliot Dresselhaus *In its* Annual Research Briefs, 1992 Jan. 1993 p 455-460 (For primary document see N94-12284 01-34)
Avail: CASI HC A02/MF A04

Many computer simulations in engineering and science -- and especially in computational fluid dynamics (CFD) -- produce huge quantities of numerical data. These data are often so large as to make even relatively simple post-processing of this data unwieldy. The data, once computed and quality-assured, is most likely analyzed by only a few people. As a result, much useful numerical data is under-utilized. Since future state-of-the-art simulations will produce even larger datasets, will use more complex flow geometries, and will be performed on more complex supercomputers, data management issues will become increasingly cumbersome. My goal is to provide software which will automate the present and future task of managing and post-processing large turbulence datasets. My research has focused on the development of these software tools -- specifically, through the development of a very high-level language called 'Tensoral'. The ultimate goal of Tensoral is to convert high-level mathematical expressions (tensor algebra, calculus, and statistics) into efficient low-level programs which numerically calculate these expressions given simulation datasets. This approach to the database and post-processing problem has several advantages. Using Tensoral the numerical and data management details of a simulation are shielded from the concerns of the end user. This shielding is carried out without sacrificing post-processor efficiency and robustness. Another advantage of Tensoral is that its very high-level nature lends itself to portability across a wide variety of computing (and supercomputing) platforms. This is especially important considering the rapidity of changes in supercomputing hardware. Derived from text

TOPICS IN PATTERN FORMATION AND CHAOTIC SYSTEMS Final Report

H. D. Abarbanel May 1993 5 p
(Contract N00014-89-D-0142)
(AD-A265922; MPL-U-24/93) Avail: CASI HC A01/MF A01

This project was a Joint Research Project in the study of Pattern Formation and Chaotic Dynamics by members of the Institute for Applied Physics (IPFAN) in Gorky, USSR and the Marine Physical Laboratory, at the University of California, San Diego, USA. This project involved both experimental and theoretical research in the topic of interest. At both IPFAN and UCSD the scientists have investigated the creation of patterns in spatio-temporal systems and the chaotic dynamics of these systems in several specific examples: (1) Dynamics of Surface Waves, Variation on the classical Faraday experiment; (2) Surface tension induced convection, Benard-Marangoni Convection; (3) Vortex eneration in the wakes of bluff bodies; and (4) Boundary layer chaos and transition in turbulence. SUPPRESSION OF THE NEAR WALL BURST PROCESS OF A FULLY DEVELOPED TURBULENT PIPE FLOW

A. A. Fontaine and S. Deutsch May 1993 229 p
(Contracts N00014-91-J-1064; N00014-91-J-1608)
(AD-A265995; TR-93-06) Avail: CASI HC A11/MF A03

A local suppression of the near wall region burst process is achieved by modifying the buffer region and sublayer (Y+ less than 30) of a fully developed turbulent pipe flow with a 16.4 wall unit high, wall-mounted bump. A downstream converging flow field is produced by the divergence of the approaching mean flow around the bump. In addition, a pair of counter-rotating vortices are generated by the bump and convected downstream. The vortices have a circulation which produces a common wall directed flow between them, which also contributes to the flow convergence. These vortices are 10 to 15 wall units in diameter and persist for more than 174 wall units downstream. The investigation is conducted in the ARL/PSU glycerin tunnel at a Reynolds number, based on pipe diameter, of approximately 10,000. The momentum thickness Reynolds number is 730. Multicomponent, multi-point, time resolved laser Doppler velocimetry measurements are made in both the undisturbed and modified boundary layers. The measurements include single-point three-component velocity profiles, two-point multi-component velocity correlations and velocity spectral estimates. DTIC

TOWARDS A CELL-VERTEX NAVIER-STOKES ALGORITHM FOR THREE-DIMENSIONAL STRUCTURED/UNSTRUCTURED MESHES

A. J. Peace Apr. 1992 10 p Presented at the ICFD Conference on Numerical Methods for Fluid Dynamics, Reading, England, 7-10 Apr. 1992
(Contract SLS41B/2437)
(ARA-Memo-366) Avail: CASI HC A02/MF A01

The achievements made in the move towards an efficient Navier-Stokes algorithm for three-dimensional structured/unstructured meshes are described. These achievements can be divided into three main areas - a three-dimensional Euler algorithm for general meshes, a multi-grid technique for block-structured meshes, and a Navier-Stokes algorithm for two-dimensional general meshes. Outlines of the methods used, demonstration examples, and a discussion of remaining problems are included. Author (revised)

COMPILATION OF PROPOSALS FOR BOILING AND EVAPORATION EXPERIMENTS IN SPACE ENVIRONMENTS AND PROPOSALS CONCERNING EXPERIMENT PROJECTS [UCHUU KANKYOUKA NI OKERU FUTTOU JOUHATSU JIKKEN TEIAN NO SEIRI TO JIKKEN KEIKAKU NI KANSURU TEIAN]

Humito Kaminaga and Kouichi Chiba (Ishikawajima-Harima Heavy Industries Co. Ltd., Tokyo, Japan.) *In its* The Third Workshop on Two Phase Fluid Experiment in the Space Environment 31 Mar. 1993 p 14-17 In JAPANESE Sponsored in cooperation with Boiling Evaporation Group, Japan (For primary document see N94-12547 01-34)
Avail: CASI HC A01/MF A02

An overview of the results of the compilation of proposals for boiling and vaporization experiments in the space environment and experiment plans is presented. The results of boiling an vaporization experiment in space proposal compilation, proposals on the experiments, and items to be considered in conducting the experiments are outlined. In utilizing boiling heat transmission in space, some kinds of forced flow patterns are necessary. Items which must be made clear in boiling phenomena in microgravity are as follows: (1) developed nuclear boiling heat transmission and burnout thermal flux; (2) boiling and vaporization heat transmission when convection effects are not so large due to comparatively low flow rate; and (3) unstable boiling phenomena such as flushing. The following activities are deemed necessary to boil down the experiment projects: (1) equipment requiring forced heat rejection and its structure; (2) thermal conditions; (3) appropriate working fluid; and (4) appropriate heat transmission. MODELING VOID GROWTH AND MOVEMENT WITH PHASE CHANGE IN THERMAL ENERGY STORAGE CANISTERS
Douglas Darling, David Namkoong, and J. Raymond Lee Skarda Jul. 1993 12 p Presented at the 28th AIAA Thermophysics Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA Previously announced in IAA as A93-46569
(RTOP 506-41-31)
(NASA-TM-106288; E-8026; NAS 1.15:106288; AIAA Paper 93-2832)
Avail: CASI HC A03/MF A01

A scheme was developed to model the thermal hydrodynamic behavior of thermal energy storage salts. The model included buoyancy, surface tension, viscosity, phases change with density difference, and void growth and movement. The energy, momentum, and continuity equations were solved using a finite volume formulation. The momentum equation was divided into two pieces. The void growth and void movement are modeled between the two pieces of the momentum equations. Results showed this scheme was able to predict the behavior of thermal energy storage salts. Author

Spray forming is a multiphase fabrication technology in which a spray of finely atomized liquid droplets is directed onto a suitably shaped substrate or pattern to produce a coherent, near-net-shape deposit. The technology can simplify materials processing where simultaneously improving product quality. Researchers at the Idaho National Engineering Laboratory (INEL) are developing spray-forming technology for producing near-net-shape solids and coatings of a variety of metals, polymers, and composite materials using de Laval nozzles. Here we briefly describe the flow field characterization and atomization behavior of liquid metals in linear de Laval nozzles, and illustrate their versatility by summarizing results from three spray-forming programs. In one program, low-carbon steel strip greater than 0.75 mm was produced. In another program, polymer membranes approximately 5 microns thick were spray formed. Finally, recent results in spray forming molds, dies, and related tooling for rapid prototyping are described. DOE

DNS ON CONTROL OF LAMINAR-TURBULENT TRANSITION IN CHANNEL FLOW WITH SUCTION AND BLOWING [SUIKOMI FUKIDASHI NIYORU CHANNERURYUU SENI SEIGYO NO DNS]
Kiyoshi Yamamoto, Takeo Murase (Fujitsu Ltd., Tokyo, Japan.), and J. M. Floryan (University of Western Ontario, London.) *In its* Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 5-9 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

Numerical simulation of laminar-turbulent transition in channel flow with spatially periodic suction/blowing from its channel walls is conducted with a spectral method based on the Fourier spectral method. Reynolds number is fixed on a subcritical value, 5,000, and the influence of both amplitude and wave number of the suction/blowing on the transition is investigated. When the amplitude is small, the transition does not occur because the suction/blowing gives only a slight effect to the basic flow and the resulted flow remains stable to all three-dimensional small disturbances. On the other hand, when the amplitude is a large value, the transition occurs in a finite time, and finally it is obtained instantaneously with a huge value of the amplitude. It is found that the suction/blowing makes the separation ridges on the wall, which may simulate a wall roughness. The transition times are obtained for the moderately large amplitudes and wave numbers, obey nearly a minus two power law dependence on the ratio of amplitude to wave number. Author (NASDA)

AERODYNAMIC SOUND DUE TO INTERACTION BETWEEN A TWO-DIMENSIONAL FREE SHEAR LAYER AND THE LEADING EDGE OF A PARALLEL FLAT PLATE [NIJIGEN SENDANSOU TO HEIBAN NO KANSHOU NIYORU HASSHIN TO KUURIKION] c71
Fujihiko Sakao *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 15-22 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A02/MF A02

Sound is generated aerodynamically when the leading edge of a flat plate is set in the middle of a free shear layer. The mechanism for it is a self-maintaining oscillation based on a feedback loop including perturbation of the shear layer by sound at the nozzle lip, developments of the perturbation downstream, and sound generation at the edge by passing of the perturbed vorticity. Due to absence of acoustic resonance in the present set up, any change in parameters results in smooth, continuous, and wide-ranged changes in the outcome, unlike in previous experiments, where changes are often sticky, discontinuous, and with hysteresis. It seems that there are more than two different mechanisms, and either of them appears according to the conditions. Among the conditions is whether the shear

layer from the nozzle to the edge is laminar or turbulent is very important.

FLUCTUATIONS OF LONGITUDINAL VORTICES ALONG A CONCAVE WALL [OUKYOKUMEN NI SOU TATEUZU NO YURAGI] **c02**
Akira Ito and Yasuyuki Fukutomi *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 23-24 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

The fluctuations of the longitudinal vortices along a concave wall of one m in radius were visualized by smoke and measured by hot-wire anemometer at a free air stream velocity ranging from two to five m/sec. It was shown that the magnitude of such fluctuations increased as the length of straight channel set in front of the concave channel increased. The experiments were carried out by three straight channels of 200 mm, 800 mm, and 1,600 mm in length. The relation between the fluctuation behavior and the turbulence intensity of the free stream flow in the straight channel were investigated. Author (NASDA)

EXPERIMENT ON A HIGH REYNOLDS NUMBER TURBULENT BOUNDARY LAYER [KOU REINORUZUSUU RANRYUU KYOUKAISOU NO JIKKEN]
Yuu Fukunishi, Yasuaki Kohama, and Ryouji Kobayashi *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 25-28 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

A smooth roof of a high-speed train was used to investigate turbulent boundary layers at high Reynolds number. A total of 19 hot-wire probes were used simultaneously to obtain data. Conditional sampling technique was applied to the data in order to investigate the features of coherent structures in turbulent boundary layers at high Reynolds numbers.

ON THE WAKE BEHIND A HIGH SPEED TRAIN [KOUSOKU SOUKOU SHARYOU NO HANRYUU]
Muneshige Okude, Hidetoshi Hayafuji, and Tatsuya Matsui (Gifu Univ., Japan.) *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 29-32 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

The velocity distributions in the boundary layer on the side wall of a high speed train were measured by using two rakes of the multiple hot-wires. One was set on the wall of the last car of a train which was running at 320 km/hr on the downway railroad, the other was set on the nose of the first car of a train which was at rest on the upway railroad. The instant the two rakes of multiple hot-wire came in a straight line, and the velocity distribution throughout the boundary layer could be obtained. After that instant, the velocity distributions in the outer part of the wake behind the running train were measured by the stationary hot-wire rake set on the car at rest. The thickness of the boundary layer on the wall of the last car was about 2.5 m. The spectrum of the velocity fluctuations in the wake had strong intensity at about 1.5 and 3.5 Hz in its distribution. The flow pattern in the wake was visualized by using the smoke generated by smoke markers. Recording of the wake flow by a video camera was not successful, but the naked eye observation noticed the alternating vortex shedding from the rear surface of the last car as in the case of an automobile. The flow patterns on the rear surface of the last car visualized by the tuft method also showed the alternating vortex shedding. The shedding frequency could be roughly about two to five Hz. CALIBRATION OF ANEMOMETERS AT LOW SPEED BY MEANS OF TOWING CARRIAGE [SOUKOU DAISHA WO MOCHIITA TEISOKUIKI DENO FUUSOKUKEI NO KOUSEI] **c35**
Yoshiya Terao *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 33-35 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

A towing carriage system for anemometers in the range below one m/sec is described. Anemometers under calibration are set on the carriage which moves on the 45 meter long rails through stationary air at a constant speed between 0.05 and 1.00 m/sec. The output of the anemometers are calibrated against the carriage velocity. Author (NASDA)

CRITERIA FOR ONSET OF BOUNDARY-LAYER TRANSITION ON SPINNING BODIES [KAITENTAI MAWARI NO SANJIGEN KYOUKAISOU NO FUANTEISEI NITSUITE]
Yasuaki Kohama *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 37-40 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

Boundary-Layers on spinning axisymmetric bodies become unstable much earlier than two-dimensional cases owing to centrifugal or crossflow instabilities. There is no reliable parameter up to now with which the onset condition of turbulent transition is predicted. Considering local flow conditions on a spinning cone, together with Goertler instability condition on a concave wall, criteria for the onset condition on spinning bodies is discussed.

ON THE FORMATION PROCESS OF KARMAN VORTEX STREET [KARUMAN UZURETSU NO KEISEI KATEI NITSUITE] **c02**
Michio Nishioka *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 41-45 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

An experimental study is conducted on the formation process of a Karman vortex street. The growth of wave-disturbances into the vortex street is examined by introducing initially small-amplitude disturbances using a loud-speaker, at a cylinder Reynolds number, R = 3.2 x 10(exp 3). On the basis of the results of mu-fluctuation measurements and stability calculations, it is shown that the formation process is initially controlled by wave-disturbances similar to those of symmetric mu, which evolve into the antisymmetric type downstream and eventually into the vortex street. Thus, the process is quite complex, and a further careful and detailed study is required to obtain a better understanding of the mechanism of vortex formation, especially in terms of the absolute instability. CURVATURE EFFECTS IN THREE-DIMENSIONAL BOUNDARY LAYERS
R.-S. Lin and H. L. Reed (Tohoku Univ., Sendai, Japan.) *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 51-53 Sponsored by NASA. Langley Research Center (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

The effect of including wall and streamline curvature terms in swept-wing boundary-layer stability calculations is studied. The linear disturbance equations are cast on a fixed, body-intrinsic, curvilinear coordinate system.

Those nonparallel terms which contribute mainly to the streamline-curvature effect are retained in this formulation and approximated by their local finite-difference values. Convex wall curvature has a stabilizing effect, while streamline curvature is destabilizing. Author (NASDA)

SIMULTANEOUS 3D TURBULENT LARGE-SCALE STRUCTURES IN A FLOOD FLOW BY MULTI-CHANNELS MEASURING SYSTEM [KOUZUIJI NO JITSU KASEN DENO MIDARE NO SHUNKANZOU NO KEISOKU]

Mikio Hino, Yang Meng, and Nobuyoshi Murayama *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 55-58 In JAPANESE (For primary document see N94-12611 01-34)

Avail: CASI HC A01/MF A02

Field measurements on turbulent large-scale structure of a flood flow in the Hinuma river at a high Reynolds number of the order of 10(exp 6) were conducted with 16-channel electromagnetic velocimeters. The turbulent velocity components (u, v) at eight points in a plane perpendicular to the mean flow have been sampled and recorded simultaneously by a A/D converter. The quasi-instantaneous 3D images of coherent structures in the flood flow were reconstructed from these data by using a new method of data analysis. These structures detected near the river bed are low-velocity lumps of fluid and generate intermittently peaks of the high positive Reynolds stress. The high concentration of the suspended load in the flood flow may be explained by these structures. Near the water surface, the coherent structure has also been found and they generated small-scale boils. Author (NASDA)

A NUMERICAL EXPERIMENT OF BOUNDARY LAYER TRANSITION AT SUBCRITICAL REYNOLDS NUMBERS [ARINKAI KYOUKAISOU SENI NO SUUCHI JIKKEN]

Makoto Asai *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 59-62 In JAPANESE (For primary document see N94-12611 01-34)

Avail: CASI HC A01/MF A02

In order to clarify the mechanism of wall turbulence generation, the response of boundary layer to strong disturbances at subcritical Reynolds numbers is investigated through a direct numerical simulation. To trigger the subcritical transition, a discrete vortex is initially introduced upstream of the leading edge of boundary-layer plate. The preliminary results on the excited vortical flow structures and on the deformation and viscous damping of vortices are presented. Author (NASDA)

TURBULENT DRAG REDUCTION OF A d-TYPE ROUGH WALL BOUNDARY LAYER WITH LONGITUDINAL RIBS PLACED WITHIN THE GROOVES [TATERIBU NIYORU D-GATA SOMEN RANRYUU KYOUKAISOU NO TEIKOU GENSHOU]

Hideo Oosaka and Shinsuke Mochizuki *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 67-70 In JAPANESE (For primary document see N94-12611 01-34)

Avail: CASI HC A01/MF A02

In order to control the turbulent energy production and transport processes due to the coherent vortices associated with the bursting phenomenon in a d-type rough wall turbulent boundary layer, longitudinal thin ribs were placed within the transverse grooves with a suitable spanwise spacing. Direct measurements of the local skin friction coefficient evidently show the effectiveness of drag reduction using the longitudinal ribs. Maximum drag reduction rates to d-type rough wall flow and to smooth wall flow are minus 10 percent and minus 3 percent, respectively. The drag reduction rate can be reasonably expressed in terms of the rib Reynolds number. Comparisons of some mean flow properties between the modified flow and the d-type rough wall flow provide evidence that the present passive control device reduces the turbulent energy production rate. INSTABILITY AROUND AN ISOLATED ROUGHNESS ELEMENT [KORITSU SODO MAWARI NO FUANTEISEI]

Tatsuo Motohashi *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 75-77 In JAPANESE (For primary document see N94-12611 01-34)

Avail: CASI HC A01/MF A02

Detailed measurements were made of the flow field around an isolated roughness element. High shear layers generated in the near wake of the roughness element were disclosed through the hot wire measurements. In the region immediate behind the roughness, the shear stress in the vertical direction is responsible for the instability. On the other hand, the spanwise distribution of shear stress begins to play a dominant role in the transition process in the downstream region. Author (NASDA)

GROWTH AND BREAKDOWN OF TAYLOR-GOERTLER VORTICES IN ROTATING BLASIUS BOUNDARY LAYER [KORIORIRYOKU BA NIOKERU TERA-GERUTORA UZU NO SEICHOU TO HOUKAI]

Masaharu Matsubara and Shigeaki Masuda *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 83-86 In JAPANESE (For primary document see N94-12611 01-34)

Avail: CASI HC A01/MF A02

The Coriolis force normal to the wall causes Taylor-Goertler vortices in a boundary layer rotating around the spanwise axis. These vortices distort the basic Blasius boundary layer into an inflectional distribution that should be inviscidly unstable. The experimental results showed that the pitch of Taylor-Goertler vortices are independent of the given initial disturbance, and suggested some mechanisms to select the spanwise pitch. The velocity fluctuation was rounded near the inflectional point of the spanwise velocity distribution, though it was not clear whether it was caused by the inviscid inflectional instability or by the spanwise fluctuation of the Taylor-Goertler vortex itself. TRAVELING DISTURBANCES APPEARING IN YAWED CYLINDER BOUNDARY LAYER TRANSITION [KEISHA ENCHUU KYOUKAISOU SENI NIOKERU SHINKOUHA FUANTEISEI NITSUITE]
Yasuaki Kohama *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 87-89 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

Unsteady disturbances with two different frequency f(sub 1) and f(sub 2) were detected in the boundary layer transition process on a yawed cylinder surface. Detailed velocity field measurement were performed using rotatable hot wire system. It was found that the high frequency(f(sub 2)) disturbance seems to be a streamwise inflectional instability that appears locally over the top of each of the crossflow vortices and drives the flow field directly into a full turbulent state. Directions and phase velocities of these disturbances were measured and it was found that the high frequency disturbance (f(sub 2)) is the secondary instability which was visualized by smoke previously. VISUAL STRUCTURE OF KARMAN VORTEX STREETS IN A ROUTE TO CHAOTIC STATES EXCITED BY OSCILLATION OF A CIRCULAR CYLINDER [KAOSU IKOU KATEI NIOKERU KARUMAN UZURETSU NO SHIKAKU KOUZOU] **c02**
Hiroshi Nagata and Takashi Ishimaru *In* NAL, Proceedings of the 9th and 10th NAL Workshop on Investigation and Control of Boundary-Layer Transition Nov. 1992 p 91-95 In JAPANESE (For primary document see N94-12611 01-34)
Avail: CASI HC A01/MF A02

The structure of Karman vortex streets formed behind a circular cylinder oscillated in the streamwise direction was studied by using flow visualization and hot-film anemometry. The spectra of the velocity fluctuation at one point, which is located immediately downstream of the absolute instability region, were found to correspond intimately to the global structure of the vortex street. The chaotic vortex streets appear in the two ranges both around the lower and the upper boundaries of the lock-in range for the frequency of the cylinder oscillation. In the ranges outside the lock-in and the chaotic ranges, the velocity fluctuations become quasi-periodic states. The variation of the structure of the vortex streets can be interpreted as a result of nonlinear interaction between the pattern created by the oscillation of the cylinder and the pattern formed by natural shedding of the vortices. The chaotic vortex streets are considered to develop under the unsteady states in a competition between these two patterns. Author (NASDA)

(NASA-CR-194191; NAS 1.26:194191; RTR-214-01-Vol-2) Avail: CASI HC A04/MF A01

The Plume Impingement Program (PLIMP) is a computer code used to predict impact pressures, forces, moments, heating rates, and contamination on surfaces due to direct impingement flowfields. Typically, it has been used to analyze the effects of rocket exhaust plumes on nearby structures from ground level to the vacuum of space. The program normally uses flowfields generated by the MOC, RAMP2, SPF/2, or SFPGEN computer programs. It is capable of analyzing gaseous and gas/particle flows. A number of simple subshapes are available to model the surfaces of any structure. The original PLIMP program has been modified many times of the last 20 years. The theoretical bases for the referenced major changes, and additional undocumented changes and enhancements since 1988 are summarized in volume 1 of this report. This volume is the User's Input Guide and should be substituted for all previous guides when running the latest version of the program. This version can operate on VAX and UNIX machines with NCAR graphics ability. Derived from text

DEMONSTRATION PROTOTYPE GAMMA-RAY HODOSCOPE ALTERNATIVE TO CARGOSCAN FOR ROCKET STAGE MONITORING
C. E. Dickerman, R. E. Boyar, J. P. Regis, and D. J. Travis Nov. 1992 57 p
(Contract W-31-109-eng-38)
(DE93-006908; ANL/ACTV-92/2) Avail: CASI HC A04/MF A01 (US Sales Only)

The potential of the gamma-ray hodoscope as a less expensive and less intrusive alternate to CARGOSCAN for rocket stage monitoring was demonstrated in measurements with a full-scale prototype gamma-ray hodoscope system. After preliminary tests at Argonne and other laboratories, the system was shipped to the Technical On-Site Inspection (TOSI) simulation facility at Albuquerque NM, and used for a series of 'blind' tests conducted under the supervision of Sandia and Brookhaven personnel. A low-level Co-60 source was adequate for hodoscope determination of the locations of the diameter and end edges of the rocket motor items inside a missile-shipping railcar. The system was not fooled by the 'simple spoofing' attempts made during the TOSI runs. However, most of the 'complex spoofing' attempts were successful with this low-resolution system. Although not optimized for portable service, the prototype was unpacked and set up by the three-person ANL team within four hours, and taken down and packed by the same team within four hours. The prototype was returned to Argonne, where the detector arrays were reconfigured and used successfully to detect a complex spoofing simulation in which an SS-20 is loaded inside an SS-25 shell, and the annulus outside the SS-20 is packed with material at solid-fuel density. The hodoscope uses a technology proven by over twenty-five years experience; it does not require a complex accelerator or large expensive gamma-ray detectors. As a result of its modular, commercial, off-the-shelf technology, the hodoscope is expected to be more reliable, much lower in cost, and less intrusive than the CARGOSCAN (trademark) as applied to either fixed portal monitoring or portable on-site inspection of rockets and other treaty-limited items. The level of hodoscope resolution may be adjusted, in a trade-off between intrusiveness and resistance to complex spoofing attempts, as part of a suitably defined inspection system. DOE

SURFACE AND NEAR-SURFACE ATOM IMAGING WITH PHOTOELECTRON HOLOGRAPHY
L. J. Terminello, J. J. Barton (IBM Research Lab., Yorktown Heights, NY.), and D. A. Lapiano-Smith (IBM Research Lab., Yorktown Heights, NY.) Jul. 1992 8 p Presented at the 10th International Conference on Vacuum Ultraviolet Radiation Physics, Paris, France, 27-31 Jul. 1992
(Contracts W-7405-eng-48; DE-AC02-76CH-00016)
(DE93-013197; UCRL-JC-111627; CONF-920735-6) Avail: CASI HC A02/MF A01

Near-surface atoms from a Cu(001) surface were imaged using 3p photoelectron holograms. The angle-dependent electron diffraction patterns that constitute an electron hologram were Fourier transformed to create a three dimensional, real-space image of the scattering atoms. We have made use of a multiple-wavenumber, phased summing method to improve the atom imaging capabilities of experimental photoelectron holography using the Cu(001) prototype system. DOE

TEST OF A METHOD FOR PHASE RETRIEVAL IN HRTEM
M. J. Beeching and A. E. C. Spargo 1992 2 p Presented at the 27th Annual Meeting of the Microbeam Analysis Society and the 19th Annual Meeting of the Microscopial Society of Canada, Boston, MA, 1 Aug. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-612641; UM-P-92/21; CONF-9208150) Avail: CASI HC A01 (US Sales Only)

Several methods of phase retrieval from the high resolution transmission electron microscopy image intensity distributions have been proposed but no standard method has emerged. The results achieved using a technique based on a development of the focus variation method, are reported. The dependence of the retrieved wavefunction on various experimental parameters is investigated and the method tested using computer simulated images. The method is shown to be useful in finding the complex wavefield at the exit surface of the specimen but the relationship of this to the specimen structure is considered as a separate issue. DOE

DESIGN AND DEVELOPMENT OF A MINIATURE COLUMN-BASED INTERFACE (MCBI) STRESS GAGE Final Report, Jan. - Nov. 1988
Denis D. Rickman Apr. 1993 145 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DNA-MIPR-88-503)
(AD-A266054; WES/TR/SL-93-3) Avail: CASI HC A07

Tests are routinely conducted to evaluate the survivability, under simulated battlefield conditions, of buried military structures subjected to high-explosive loadings. The survivability assessments require the measurement of dynamic normal stresses induced at soil/structure interfaces. Stresses in excess of 10,000 psi and accelerations greater than 100,000 g's may be applied at interface locations. Normal-incidence interface stress gages currently used in such tests are incapable of accurately measuring stresses above 5,000 psi, and are sensitive to lateral accelerations and structure-transmitted stresses which distort the measurement. This study explores the design, development, and testing of a miniature, column-based, interface (MCBI) stress gage. The MCBI gage is designed to measure normal stresses up to 35,000 psi. Laboratory tests indicate that the gage produces a linear output due to applied pressure and is virtually insensitive to lateral stresses. Explosive tests have shown the MCBI gage compares favorably to commonly-used interface stress gages at stresses up to 3,000 psi and is survivable at stresses up to 25,000 psi. DTIC

DEVELOPMENT AND TESTING OF A SUPERCONDUCTING LINK FOR AN IR DETECTOR Final Technical Report, Jul. 1989 - Apr. 1991
R. Caton and R. Selim 1991 10 p
(Grant NAG1-1042)
(NASA-CR-193674; NAS 1.26:193674) Avail: CASI HC A02/MF A01

The development and testing of a ceramic superconducting link for an infrared detector is summarized. Areas of study included the materials used, the electrical contacts, radiation and temperature cycling effects, aging, thermal conductivity, and computer models of an ideal link. Materials' samples were processed in a tube furnace at temperatures of 840 C to 865 C for periods up to 17 days and transition temperatures and critical current densities were recorded. The project achieved better quality high superconducting transition temperature material through improved processing and also achieved high quality electrical contacts. Studies on effects of electron irradiation, temperature cycling, and aging on superconducting properties indicate that the materials will be suitable for space applications. Various presentations and publications on the study's results are reported. CASI

DESIGN OF CCD CAMERA SYSTEM FOR USE INSIDE ELECTRON BEAM FURNACE
J. S. Sze Oct. 1992 16 p Presented at the Electron Beam Melting and Refining Conference, Reno, NV, 25-27 Oct. 1992
(Contract W-7405-eng-48)
(DE93-009525; UCRL-JC-111578; CONF-9210282-2) Avail: CASI HC A03/MF A01

The design of a wide dynamic range camera system for use inside Electron Beam furnaces is presented. The camera system is designed for use in high vacuum and in a high radiant heat flux environment looking directly into a high metallic vapor flux. In addition, the camera is designed to have a dynamic range that can provide a good image in both low light level conditions as well as in high brightness situations such as when the electron beam is impinging on the melt surface. An analysis is given for estimating the dynamic range of the camera imaging system and the camera cooling requirements. Techniques for capturing and recording video images are also presented. The application of various optical filters and liquid crystal variable attenuators for the camera imaging system is discussed. DOE

HEAT FLUX MEASUREMENTS ON CERAMICS WITH THIN FILM THERMOCOUPLES
Raymond Holanda, Robert C. Anderson, and Curt H. Liebert Nov. 1993 15 p Proposed for presentation at the SEM Fall Conference Structural Testing Technology at High Temperature, Ojai, CA, 8-10 Nov. 1993; sponsored by the Society for Experimental Mechanics
(RTOP 505-62-50)
(NASA-TM-106305; E-7963; NAS 1.15:106305) Avail: CASI HC A03/MF A01

Two methods were devised to measure heat flux through a thick ceramic using thin film thermocouples. The thermocouples were deposited on the front and back face of a flat ceramic substrate. The heat flux was applied to the front surface of the ceramic using an arc lamp Heat Flux Calibration Facility. Silicon nitride and mullite ceramics were used; two thicknesses of each material was tested, with ceramic temperatures to 1500 C. Heat flux ranged from 0.05-2.5 MW/m2(sup 2). One method for heat flux determination used an approximation technique to calculate instantaneous values of heat flux vs time; the other method used an extrapolation technique to determine the steady state heat flux from a record of transient data. Neither method measures heat flux in real time but the techniques may easily be adapted for quasi-real time measurement. In cases where a significant portion of the transient heat flux data is available, the calculated transient heat flux is seen to approach the extrapolated steady state heat flux value as expected. Author (revised)

HOLOGRAPHIC MULTIPLEXING FOR 3D OPTICAL MEMORY Final Report
V. R. Domash Jun. 1993 26 p
(Contract F49620-92-C-0077)
(AD-A266099; AFB-0077-FM-9566-624; AFOSR-93-0414TR) Avail: CASI HC A03/MF A01

The increasing demand for larger memory capacity has led to the exploration of volume data storage in optical materials with theoretical capacities of 10 to the 13th power bits/cm cubed. However, an important technical barrier is the design of an input/output architecture to read and write to the optical 3D memory at very high speed. During Phase 1 of this effort, we have experimentally demonstrated the operation of a unique optical lock-in instrument that can play a key role in accessing optical memories at high data rates. This optical lock-in detector is capable of demultiplexing a highly complex wavefront consisting of a number of holograms that have been combined on a single light beam. Using the optical lock-in detector, it is possible to demultiplex and recover any individual hologram using optical mixing in a photorefractive medium with the appropriate modulation applied to the reference optical beam. For Phase 2 a prototype optical memory system is proposed, including highly parallel input/output techniques, a cache memory for faster access, and a unique photorefractive material for optical data storage. At least one key component of this optical memory system, an optical beamlet array generator, is a likely candidate for Phase 3 development by Foster-Miller and Polaroid Corporation. DTIC

INTEGRATING THE SERVICES' IMAGERY ARCHITECTURES Study Project Report
John F. Mader 15 Apr. 1993 137 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265487) Avail: CASI HC A07

Any military organization requiring imagery must deal with one or more of several architectures: the tactical architectures of the three military departments, the theater architectures, and their interfaces to a separate national architecture. A seamless, joint, integrated architecture must meet today's imagery requirements. The CIO's vision of 'the right imagery to the right people in the right format at the right time' would serve well as the objective of a joint, integrated architecture. A joint imagery strategy should be initially shaped by the four pillars of the National Military Strategy of the United States: strategic deterrence; forward presence; crisis response; and reconstitution. In a macro view, it must consist of a series of sub-strategies to include science and technology and research and development, maintenance of the imagery related industrial base, acquisition, resource management, and burden sharing. Common imagery doctrine must follow the imagery strategy. Most of all, control, continuity, and direction must be maintained with regard to organizations and systems development as the architecture evolves. These areas and more must be addressed to reach the long term goal of a joint, integrated imagery architecture. This will require the services and theaters to relinquish some sovereignty over at least systems development and acquisition. Nevertheless, the goal of a joint, integrated imagery architecture is feasible. The author presents arguments and specific recommendations to orient the imagery community in the direction of a joint, integrated imagery architecture. DTIC

ANALYSIS OF HOPKINSON BAR PRESSURE GAGE Final Report
James T. Baylot Jan. 1993 68 p
(AD-A262366; WES/TR/SL-93-1) Avail: CASI HC A04/MF A01

In order to fully understand the results of experiments on buried structures subjected to high intensity airblast that simulates nuclear weapons effects, an accurate measurement of the airblast pressure time-history must be made. Quite often, the peak airblast pressures in these tests are above what commercially-available air-pressure gages are capable of measuring. Hopkinson bar pressure gages remain elastic while measuring these very high airblast pressures. These bar gages also have the advantage that the sensing element of the gage is placed at a distance down the bar from the high pressure airblast. Thus the sensing element and the wires attached to it stand a much better chance of surviving the environment created by the simulator. The U.S. Army Engineer Waterways Experiment Station (WES) has developed a bar gage, designed to measure the airblast for tests in which airblast-induced ground shock is simulated. The primary objective of this study was to determine the accuracy of the WES bar gage and the possible effects the water and water seal have on the measured waveforms. Other objectives are to evaluate the differences in measured stresses between the WES and NMERI bars in the DET test, and to determine if modifications to the WES bar gage design are needed. AN OPTOELECTRONIC GRAPHICS DISPLAY PROCESSOR Quarterly Report, 15 Mar. - 14 Jun. 1993
Vincent P. Heuring 14 Jun. 1993 2 p
(Contract N00014-93-1-0419)
(AD-A266011) Avail: CASI HC A01/MF A01

The first three months of this grant period have seen significant progress toward the project goals. A one bit optoelectronic counter has been constructed as prototypical of an optoelectronic control unit. The counter runs at 305 MHz, and provided us much information on the timing and synchronization of such processors. We are beginning our work on developing or acquiring the optoelectronic integrated circuits and holographic optical elements that are necessary to the development of the optoelectronic graphic display processor, OGDP. We have also begun work on a CAD system for designing and constructing such processors. The CAD efforts have begun with development of algorithms for computing bit error rate in these systems. We are also in the midst of developing the logical architecture for the OGDP, including control unit and front end processor design. DTIC

DEVELOPMENT OF THE ONE-COMPONENT DIODE-ARRAY VELOCIMETER Final Report
Jun. 1993 91 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1292)
(AD-A265552; VPI-AOE-201) Avail: CASI HC A05

A new optical flow measurement technique, the diode array velocimeter (DAV), has been proposed. A DAV works by timing the passage of seed particles through a small section of a light beam. This is achieved by imaging light scattered by the particles on to one or more photodiode arrays. The arrays have a few carefully shaped elements, the shapes and positions of the elements are used to control the measurement volume geometry and thus select the measurement made. Measurement volumes sensitive to velocity, position, and acceleration may be designed. Measurements in highly turbulent and reversing flows are possible. A DAV for one-component velocity measurements has been developed to demonstrate this concept. This device uses a single laser beam to illuminate particles and a photodiode array with two rectangular elements to sense their motion. The sensitivity of this device to electrical noise in the photodiode circuitry is analyzed and found to decrease with reduction in measurement volume size. The angle response is also studied and, depending on the signal processing used, found to be closely cosinusoidal to about 60 deg. Changes to the photodiode array design could substantially increase this limit. DTIC

START-UP IMPRINTING AND SHOCK DYNAMICS IN LASER-TARGET INTERACTION
M. H. Emery 10 Dec. 1992 27 p
(Contract DE-AI03-79DP-40092)
(DE93-008051; NRL/MR-6440-92-7174) Avail: CASI HC A03/MF A01 (US Sales Only)

Improved uniformity of the laser focal spot profile is a necessary criterion for the success of high intensity laser fusion and to improve the quality of data from moderate intensity laser driven shock experiments in solids. Recently developed laser smoothing techniques rely on both temporal smoothing and thermal smoothing to produce uniform ablation pressures on the target surface. Thermal smoothing is not effective during the low intensity portion of a laser pulse and the resultant shock structure mirrors the residual laser nonuniformities. The impact of the first (nonuniform) shock can be diminished by using foam layers, a precursor x-ray flash, shallow angles of incidence, and by adiabatically compressing the target with a temporally long, slowly rising laser pulse. The primary purpose of this trip was to present two invited lectures at the Second Venezuelan Workshop on Laser Spectroscopy. This conference included essentially all of the Venezuelan researchers active in this area. In addition, four speakers from outside of Venezuela were invited to this meeting; two from the USA and two from the former Soviet Union (FSU). The primary topics of the meeting were fluorescence spectroscopy, photothermal spectroscopy, and laser - material interactions. Prior to the conference, three institutions in Caracas were visited (IVIC, USB, and UCV) and a presentation was given at UCV. The group of scientists and students attending the conference were interested in establishing collaborations with scientists in the USA. DOE

DYNAMICS OF DISSOCIATION VERSUS IONIZATION IN STRONG LASER FIELDS
L. F. DiMauro and B. Yang 1993 10 p Presented at the Third SILAP Conference, Hansui, Belgium, 8-14 Jan. 1993
(Contract DE-AC02-76CH-00016)
(DE93-009261; BNL-48611; CONF-930184-2) Avail: CASI HC A02/MF A01

In this paper, experimental results are presented which clearly demonstrate the effectiveness that an external field has in altering the dissociation dynamics. The experiment examines the strong-field dissociation dynamics of molecular hydrogen ions and its deuterated isotopes. These studies involve multiphoton excitation in the intensity regime of 10(exp 11)-10(exp 14) W/sq cm with the fundamental and second harmonic of a ND:YAG or ND:YLF laser system. Measurements include energy resolved electron and mass spectroscopy which provide useful probes in elucidating the interaction dynamics predicted by existing models. The example this in this paper, examines the strong-field dissociation of H2(+), HD(+), and D2(+) at green (0.5 micron) and infrared (1 micron) frequencies. The diatomic ions are formed via multiphonon ionization of the neutral precursor which is physically separable from the dissociation process. This study provides the first observation of the dynamics associated with the above threshold dissociation (ATD) process and analogies will be made with the more familiar above threshold ionization (ATI) phenomenon. DOE

LASER SYNCHROTRON SOURCE (LSS) Patent Application
Philip Sprangle, inventor (to Navy), Antonio Ting, inventor (to Navy), Eric Esarey, inventor (to Navy), Amon Fisher, inventor (to Navy), and Gerald Mourou, inventor (to Navy) 19 Feb. 1993 19 p
(AD-D015755; US-Patent-Appl-SN-020158) Avail: CASI HC A03/MF A01

The Laser Synchrotron Source (LSS) utilizes a high peak power or high average power laser to generate within a vacuum chamber a laser beam travelling in one direction to interact with an electron beam traveling in an opposite direction in order to generate high-power x-rays. A ring resonator formed by a plurality of mirrors directs the laser beam in a closed loop to impact with the electron beam to produce x-rays. Concave mirrors in the ring resonator focus the laser beam upon the point where the laser beam interacts with the electron beam to intensify the laser energy at that point. When a Radio Frequency Linear Accelerator (RF linac) is used to produce the electron beam, x-rays having a short pulse length are generated. When a betatron is used as an electron source, x-rays having a long pulse length are generated. DTIC

N94-10483# China Nuclear Information Centre, Beijing.
NUMERICAL SIMULATION OF SIDEBANDS IN FREE ELECTRON LASER OSCILLATORS
Xiaojian Shu, Wengui Ji, and Taichun Wang Mar. 1992 16 p
(DE93-612675; CNIC-00605; IAPCM-0020) Avail: CASI HC A03/MF A01 (US Sales Only)

A computer code named GOFEL-P for studying sidebands of free electron laser (FEL) oscillators was developed. Simulation results from this code are in agreement with experiments and the FELP code developed by others. The mechanism about the generation, development, hopping process, spiking mode and chaos of sidebands as well as the chirp of optical frequency has been investigated. The effect of sidebands on optical output is studied with a uniform wiggler or tapered wiggler. Methods to suppress sidebands with reducing optical cavity length or with optical filter are proposed. DOE

HIGH POWER z PINCHES AS X RAY LASER PHOTOPUMPS
T. J. Nash, R. B. Spielman, L. Ruggles, and M. Vargas 1992 15 p Presented at the 3rd International Conference on Dense z-Pinches, London, England, 19-23 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-012842; SAND-92-2804C; CONF-9304126-6) Avail: CASI HC A03

Using Saturn as a driver, we are pursuing both photoresonantly pumped and photoionization/recombination lasers. Our lasing targets are gas cells with thin windows that are pumped by a z pinch 2 cm away radiating 10 TW. In both schemes the lasant and gas fill is neon. To increase our chances of measuring the resonantly photopumped lasing transition we have introduced potassium into a sodium z pinch and have eliminated oxygen from the gas cell windows. We have measured the spatial dependence of ionization balance across the gas cell, and this measurement is consistent with propagation of a shock front across the gas cell target. We have measured blue-shifted satellites to several Li-like neon transitions that may indicate return-current driven jetting a high 1.5e8 cm/sec velocity. Using a gold z-pinch we have shown that key radiation is necessary to excite the He-like lines of neon. An attempt at a single shot gain measurement also indicates that radiation is not the only source of gas cell heating. DOE

N94-10755 Lawrence Livermore National Lab., CA.
SECOND AND THIRD ORDER NONLINEAR OPTICAL PROPERTIES OF CRYSTALLINE INORGANIC/ORGANIC COMPLEXES
H. O. Marcy (Rockwell International Corp., Thousand Oaks, CA.), L. F. Warren (Rockwell International Corp., Thousand Oaks, CA.), L. E. Davis, M. S. Webb, and S. P. Velsko Jul. 1992 8 p Presented at the 1991 Spring Materials Research Society (MRS) Meeting, Baltimore, MD, May 1991 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-011883; UCRL-JC-105732; CONF-9105418-1) Avail: CASI HC A02

Properties for members of a new class of nonlinear optical (NLO) materials which stoichiometrically incorporate organic and inorganic constituents into a single crystalline lattice are reported. Recent results for our synthetic, crystal growth, and optical studies suggest that a number of these relatively transparent 'semiorganic' compounds have significant second and/or third order NLO responses and often display favorable crystal growth morphologies. The prototype material of this class zinc tris(thiourea) sulfate, or ZTS, has a UV cutoff at about 325 nm, can be readily grown to cm(sup 3) sizes, and has been shown to be a highly efficient Type II frequency doubler for 1064 nm Nd:Yag laser radiation. ZTS also processes a moderate third order nonlinear optical response (ca. 0.1 x CS(sub 2)) which occurs on at least a picosecond time scale as determined by degenerate four-wave mixing (DFWM) experiments at 532 nm. Refractive index, second harmonic generation, and DFWM data for a number of these new compounds are presented. DOE

N94-10870# North Texas Research and Development Inst., Denton.
[CONTROLLING CHAOTIC BEHAVIOR IN CO2 AND OTHER LASERS]
Progress Report No. 1, 16 Mar. - 15 Apr. 1991
26 Apr. 1993 5 p
(Contract N00014-93-C-0051)
(AD-A264811) Avail: CASI HC A01/MF A01

Significant progress has been made in the first month in setting up the equipment in preparation for producing chaotic behavior in a CO2 laser. The project goal is to synchronize and control chaos in a CO2 and other lasers, and thereby increase the power in ensembles of coupled laser sources. One method of inducing chaotic behavior in a CO2 laser is to modulate the beam in the cavity with a frequency between 50 and 100 kHz. The project has designed two schemes to achieve this modulation. These are through the modulation of the high voltage by inductive coupling and the modulation of the beam by a CdTe electro-optic modulator (EOM). Modulation of the beam using modulation of the high voltage has been achieved in the laboratory this month. This was accomplished by modulating the high voltage on the laser using an inductor connected to the anode of the laser. Modulation of the laser plasma was confirmed by detecting modulation of the plasma with a light by using a photomultiplier tube. Analysis of the chaotic regime awaits arrival and check-out of the HgCdTe detector. DTIC

FFT-BASED METHODS FOR NONLINEAR IMAGE RESTORATION IN CONFOCAL MICROSCOPY
J. B. T. M. Roerdink 1993 17 p
(CS-9301; ETN-93-94348) Copyright Avail: CASI HC A03/MF A01

A new method for attenuation correction in three dimensional imaging by a Confocal Scanning Laser Microscope (CSLM) in the (epi)fluorescence mode was developed. The fundamental element in the approach consisted in multiplying the measured fluorescent intensity by a correction factor involving a convolution integral of this intensity, which can be computed efficiently by the Fast Fourier Transform (FFT). The resulting algorithm is one or two orders of magnitude faster than an existing iterative method, but has smaller accuracy. This latter point is improved by reformulating the problem as a statistical estimation problem. First order moment and cumulant estimators are derived leading to a nonlinear integral equation for the unknow fluorescent density which is solved by an iterative method where in each step a discrete convolution is performed using the FFT. Only a few iterations are needed. It is shown that the estimators proposed are more accurate than the existing iterative method, while retaining the advantage in computational efficiency of the FFT based approach. ESA

SEMICONDUCTOR RING LASERS
J. P. Hohimer, G. R. Hadley, G. A. Vawter, and D. C. Craft Mar. 1993 41 p
(Contract DE-AC04-76DP-00789)
(DE93-012386; SAND-92-2760) Avail: CASI HC A03/MF A01

Semiconductor ring lasers are being developed for use as direct-waveguide-coupled sources for photonic integrated circuits. This report describes the results of our research and development of this new class of diode lasers. We have fabricated and characterized semiconductor ring lasers which operate continuous-wave at room temperature with a single-frequency output of several milliwatts. Our work has led to an increased understanding of the operating behavior of these lasers and to the development of two new types of advanced devices. The interferometric ring diode laser uses a coupled-cavity structure to improve the level of single-frequency performance. And, the unidirectional ring diode laser uses an active crossover waveguide to promote lasing in a single ring direction with up to 96% of the output emitted in the preferred lasing direction. DOE

THERMAL-OPTICAL SWITCHING OF A SILICON BASED INTERFERENCE FILTER
B. H. Augustine, S. T. Feng, and E. A. Irene 4 May 1993 13 p
(Contract N00014-89-J-1178)
(AD-A265152; TR-54) Avail: CASI HC A03/MF A01

We report thermal-optical switching using a silicon based interference filter fabricated by plasma enhanced chemical vapor deposition. A five film structure using high index films of amorphous Si and low index films of SiO2 comprised the device which yielded detector limited 40 ns rise time switching. Operation is in the near infrared spectral region with probe wavelengths of 810 nm and 1.152 micrometers. A 56% contrast ratio is reported when pumped by a 10.6 micrometers CO2 pulsed laser. Lower contrast switching-was also demonstrated with a Nd:YAG pumped dye laser tunable from 600-700 nm. In addition, we have demonstrated that atomic layer thickness precision is not necessary, and suggest several improvements which can further enhance device performance. DTIC

AN ANALYTIC MODEL FOR CALCULATING PUMP-INDUCED WAVEFRONT DISTORTIONS IN LASER SLABS
M. D. Rotter, A. C. Erlandson, and R. W. McCracken Mar. 1993 16 p Presented at the Society for Optical and Quantum Electronics Conference, McLean, VA, 7-11 Dec. 1992
(Contract W-7405-eng-48)
(DE93-011953; UCRL-JC-111193; CONF-921268-1) Avail: CASI HC A03/MF A01

We have developed an analytical model to predict the pump-induced wavefront distortions in flashlamp-pumped, Nd:glass, Brewster-angle slab amplifiers. The model is based on analytically solving the time-dependent bi-harmonic equation for a thin plate to obtain the spatially and time-varying surface distortions. These distortions are then directly related to the uneven heating of the laser slab by pumping processes. Experimental verification for the model was obtained by measuring the time-dependent deflections of a small-diameter CW probe beam that had been passed through our multi-segment amplifier. Good agreement between the model and experiment was obtained. DOE

DEMONSTRATION DESIGNS FOR OPTICAL-FIELD-IONIZED PLASMA X-RAY LASERS
P. A. Amendt, D. C. Eder, R. A. London, B. M. Penetrante, and M. D. Rosen Feb. 1993 13 p Presented at the International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 16-23 Jan. 1993
(Contract W-7405-eng-48)
(DE93-009227; UCRL-JC-112924; CONF-930159-24) Avail: CASI HC A03/MF A01

Previous studies of recombination x-ray lasers based on optical-field-induced ionization have stressed the conditions necessary for high gain and high output energy efficiency in Li-like Neon. Unfortunately, the higher electron density n(sub e) necessary to realize efficient generation of 98.26 A x-rays in Li-like Neon also demands serious consideration of ionization-induced refractive defocussing. We propose a demonstration experiment of optical-field-ionized plasma x-ray lasing at 247 A in Nitrogen which can tolerate strong refractive defocussing. The relatively low ionization potential energy of approximately 98 eV in Nitrogen should result in correspondingly low residual electron temperature T(sub e) which, in turn, allows large gain at lower values of electron density. The use of low electron density provides less collisional heating as well as reduced refractive defocussing. In addition to using low electron density to mitigate refraction, we also propose the use of a wide UV laser-driver focus to give reduced transverse intensity gradients near the laser axis. Milder transverse intensity gradients lead to longer refraction lengths which effectively define the volume of x-ray lasing. These two techniques for avoiding excessive refraction are used in tandem to identify an experimental regime where x-ray lasing dominates spontaneous noise by an unambiguous margin associated with a gain-length product of five. Such a margin is predicted to be exceeded for a Li-like Nitrogen plasma with n(sub e) approximately 5 x 10(exp 19)cm(exp -3), T(sub e) approximately 10 eV, and a UV laser-driver intensity of 3 x 10(exp 16)W/sq cm with 0.25 micron wavelength and 30 microns waist radius. MULTIPLE LASER BEAM COMBINING AND PHASING USING CLOSED-LOOP CONTROL
D. R. Neal, T. G. Smith, G. R. Eisler, J. L. Wilcoxen, and R. R. Rosenthal 1992 11 p Presented at the SPIE Smart Structures and Materials Meeting, Albuquerque, NM, 31 Jan. - 4 Feb. 1993
(Contract DE-AC04-76DP-00789)
(DE93-009830; SAND-92-1896C; CONF-930171-2) Avail: CASI HC A03/MF A01

One method for scaling lasers to higher power is to build several separate amplifier chains, and then coherently combine the individual beams together. To combine the beams the pathlengths must be matched to an integer number of waves, and the tip and tilt of each beam must be the same. Since optical tolerances are fractional micrometers, a sophisticated control system must be employed to actively measure tip/tilt and piston errors, and apply real time corrections. We have developed a test bed that allows us to develop the required control algorithms for two to four beams and then scale to a larger numbers. DOE

LCLS OPTICS: SELECTED TECHNOLOGICAL ISSUES AND SCIENTIFIC OPPORTUNITIES
R. Tatchyn Mar. 1993 27 p Presented at the Workshop on Scientific Application of Short Wavelength Coherent Light Source, Stanford, CA, United States, 21 Oct. 1992
(Contract DE-AC03-76SF-00515)
(DE93-010953; SU-SLAC-Pub-6064; SU-SLAC/SSRL-0010; CONF-9210278-1) Avail: CASI HC A03/MF A01

The Stanford Linac Coherent Light Source (LCLS) promises to generate photon pulses of unprecedented brevity and peak brightness in the soft x-ray range. In this presentation selected limitations and novel opportunities for technology and science associated with the availability of such pulses will be briefly assessed. Special emphasis will be placed on possible techniques for extending the peak power density and the temporal and spectral regimes of the LCLS output radiation by orders of magnitude beyond their nominal (calculated) values and to the associated instrumentation for processing this radiation. THE LASER SECOND THRESHOLD: ITS EXACT ANALYTICAL DEPENDENCE ON DETUNING AND RELAXATION RATES
A. A. Bakasov and N. B. Abraham Nov. 1992 79 p
(DE93-619706; IC-92/390) Avail: CASI HC A05/MF A01 (US Sales Only)

An exact analysis was carried out for general analytical expressions for the second threshold of a single-mode homogeneously broadened laser and for the initial pulsation frequency at the second threshold for arbitrary physical values of the relaxation rates, and at arbitrary detuning between the cavity frequency and the atomic resonance frequency. These expressions also give correspondingly exact forms for asymptotic cases that were previously studied with some approximations. Earlier approximate results are partly confirmed and partly improved by these more general expressions. The physical status of various expressions and approximations is re-considered and specified more clearly, including an analysis of which reasonably can be attained in lasers or masers. A general analytical proof is given that for larger detuning of the laser cavity from resonance a higher value of the laser excitation is required to destabilize the steady state solution (the second threshold). Results for the minimum value of the second threshold at fixed detuning as a function of the other parameters of the system and on the dependence of the ratio of the second threshold to the first threshold as a function of detuning are presented. Minima of the second threshold and of the threshold ratio occur only if the population relaxation rate is equal to zero. The minima of the threshold ratio are shown to be bounded from above as well as from below (as functions of the relaxation rates, so long as the second threshold exists). The upper bound on the threshold ratio is equal to 17. The variation of the second threshold in the semi-infinite parameter space of the decay rates is shown at various detunings in plots with a finite domain by normalizing the material relaxation rates to the cavity decay rate. DOE

ANALYTICAL DETAILS OF THE INSTABILITY THRESHOLD OF THE LASER-LORENZ MODEL
A. A. Bakasov and N. B. Abraham (Bryn Mawr Coll., PA.) Nov. 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-619707; IC-92/391) Avail: CASI HC A03 (US Sales Only)

An exact analysis of the second threshold of a single-mode homogeneously broadened laser is given for the most general operating conditions. A general analytical proof that increasing the detuning increases the second threshold is given. An analysis of the second threshold at a fixed detuning and of the ratio of the second threshold to the first threshold reveals that the smallest values occur when the population relaxation rate is minimized. THE LASER ABLATION OF GOLD FILMS AT THE ELECTRODE SURFACE OF A QUARTZ CRYSTAL MICROBALANCE
James Perez and Brad R. Weiner May 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1829)
(AD-A265535; TR-4) Avail: CASI HC A03

We report in this letter the amount of gold removed by ablation with a pulsed laser operating at 532 and 355 nm. The removed gold was measured by using a quartz crystal microbalance as a mass detector. The results indicate that for the 532 and 355 nm pulsed laser ablation of gold thin films, 10(exp 13)-10(exp 15) atom per pulse are removed over the fluence range of 0.5-5.0 J/sq cm. The amount of ablated material is found to depend on the fluence at constant wavelength and on the wavelength at constant fluence. In addition, the mass sensitivity distribution across the quartz crystal microbalance electrode has been characterized by using the laser ablation technique. DTIC

A 1.94 MICRON LASER APPARATUS, SYSTEM, AND METHOD USING A THULIUM-DOPED YTTRIUM-LITHIUM-FLUORIDE LASER CRYSTAL PUMPED WITH A DIODE LASER Patent Application
Leon Esterowitz, inventor (to Navy) and Robert C. Stoneman, inventor (to Navy) 28 Jan. 1993 16 p
(AD-D015740; US-Patent-Appl-SN-010253; Navy-Case-72490) Avail: CASI HC A03/MF A01

A laser apparatus, system, and method include a laser crystal formed of thulium-doped yttrium-lithium-fluoride, and a laser diode arranged in proximity to the laser crystal. The laser diode is capable of emitting a first laser light which is suitable for use as a pump beam for causing lasing to occur in the laser crystal. In response to the first laser light from the laser diode, the laser crystal emits a second laser light at a wavelength which is relatively highly-absorbed by organic tissue and/or water. The second laser light is therefore well-suited to medical applications, for example, and can be used to irradiate organic tissue for medical treatment. Author (DTIC)

SUBMICROSECOND, SYNCHRONIZABLE X RAY SOURCE Patent Application
Robert Whitlock, inventor (to Navy) 31 Mar. 1993 19 p
(AD-D015745; US-Patent-Appl-SN-041388; Navy-Case-74582) Avail: CASI HC A03/MF A01

In the submicrosecond, synchronizable x-ray source a high intensity pulsed laser is focused onto negatively biased laser target, at high irradiance in a vacuum, producing high temperature plasma from which electrons are emitted. The emitted electrons are accelerated in a electric field formed by impressing a potential difference across a laser target-electron target gap. The positively biased electron collects the emitted electrons, which upon impact with the electron target cause x-rays to be emitted synchronously with the incident laser pulse. DTIC

[CONTROLLING CHAOTIC BEHAVIOR IN A CO2 AND OTHER LASERS] Progress Report No. 2, 16 Apr. - 15 May 1993
26 May 1993 5 p
(Contract N00014-93-C-0051)
(AD-A265458) Avail: CASI HC A01/MF A01

Substantial progress was made in the second month of the project in setting up the equipment and testing for the production of chaotic behavior by a CO2 laser. The project goal is to synchronize and control chaos in CO2 and other lasers and thereby, to increase the power in ensembles of coupled laser sources. Weekly Coordination Meetings of the project team were held. These meetings were well attended by the project members. Significant technical discussions regarding approaches to the data analysis and theoretical analysis have occurred. The successful experimental results described later have provided stimulus regarding theoretical considerations. Analysis of the chaotic regime in detail is awaiting the next set of experiments, and additional care is to be taken in recording data for subsequent analysis. A second CO2 laser is in the initial stages of assembly. Initial checkout of components indicates a working system should result. DTIC

In Phase 1 of the research, we computationally modelled a capillary discharge device capable of producing the necessary plasma conditions to demonstrate ASE in argon at a wavelength of about 700 A. Phase 2 of the research will involve the development and diagnosis of the experimental apparatus necessary to demonstrate ASE in argon. The scaling and modification of that apparatus to demonstrate ASE at shorter wavelengths using higher-Z materials will also be investigated. Future work will involve the development of robust multilayer cavity mirrors for shorter wavelengths to increase the overall intensity and usefulness of soft x-ray lasers. DTIC

SHORT WAVELENGTH CRYSTAL FIBER DEVICES Final Report, 1 Mar. 1989 - 28 Feb. 1993
N. Djeu Apr. 1993 24 p
(Grant AF-AFOSR-0263-89)
(AD-A265716; AFOSR-93-0396TR) Avail: CASI HC A03/MF A01

The potential of crystal fibers for the generation of short wavelength visible laser radiation was explored under this program. There were two major thrusts to this work. One of them was the search for a suitable technique to produce low loss crystal fibers. Implantation cladding of bare crystal fibers with high energy ion beams was investigated for this purpose. The other was the identification of a suitable upconversion process which would be amenable for implementation in the crystal fiber form. The upconversion laser potential of Tm:YAG was explored in this area. DTIC

POSITION AND FORCE CONTROL OF A VEHICLE WITH TWO OR MORE STEERABLE DRIVE WHEELS
D. B. Reister and M. A. Unseren Oct. 1992 34 p
(Contract DE-AC05-84OR-21400)
(DE93-012512; ORNL/TM-12193) Avail: CASI HC A03/MF A01

When a vehicle with two or more steerable drive wheels is traveling in a circle, the motion of the wheels is constrained. The wheel translational velocity divided by the radius to the center of rotation must be the same for all wheels. When the drive wheels are controlled independently using position control, the motion of the wheels may violate the constraints and the wheels may slip. Consequently, substantial errors can occur in the orientation of the vehicle. A vehicle with N drive wheels has (N - 1) constraints and one degree of freedom. We have developed a new approach to the control of a vehicle with N steerable drive wheels. The novel aspect of our approach is the use of force control. To control the vehicle, we have one degree of freedom for the position on the circle and (N - 1) forces that can be used to reduce errors. Recently, Kankaanranta and Koivo developed a control architecture that allows the force and position degrees of freedom to be decoupled. In the work of Kankaanranta and Koivo, the force is an exogenous input. We have made the force endogenous by defining the force in terms of the errors in satisfying the rigid body kinematic constraints. We have applied the control architecture to the HERMIES-3 robot and have measured a dramatic reduction in error (more than a factor of 20) compared to motions without force control. DOE

THE INTENSITY OF KNOCK IN AN INTERNAL COMBUSTION ENGINE: AN EXPERIMENTAL AND MODELING STUDY
J. S. Cowart, M. Haghooie, C. E. Newman, G. C. Davis, W. J. Pitz, and C. K. Westbrook Sep. 1992 9 p Presented at the International Fuels and Lubricants Meeting and Exposition, San Francisco, CA, 19-22 Oct. 1992
(Contract W-7405-eng-48)
(DE93-013089; UCRL-JC-110069-Rev-1; CONF-9210140-2-Rev-1) Avail: CASI HC A02/MF A01

Experimental data have been obtained that characterize knock occurrence times and knock intensities in a spark ignition engine operating on indolene and 91 primary reference fuel, as spark timing and inlet temperature were varied. Individual, in-cylinder pressure histories measured under knocking conditions were conditioned and averaged to obtain representative pressure traces. These averaged pressure histories were used as input to a reduced and detailed chemical kinetic model. The time derivative of CO concentration and temperature were correlated with the measured knock intensity and percent cycles knocking. The goal was to evaluate the potential of using homogeneous, chemical kinetic models as predictive tools for knock intensity. DOE

PRELIMINARY SYSTEM DESIGN OF A THREE ARM CAPTURE MECHANISM (TACM) FLIGHT DEMONSTRATION ARTICLE
Otto Schaefer and Bill Stasi Apr. 1993 83 p
(Contract NAS8-36641)
(NASA-CR-192573; NAS 1.26:192573; ATS-92-2) Avail: CASI HC A05/MF A01

The overall objective of the Three Arm Capture Mechanism (TACM) is to serve as a demonstration of capability for capture of objects in space. These objects could be satellites, expended boosters, pieces of debris, etc.; anything of significant size. With this capability we can significantly diminish the danger of major collisions of debris with valuable space assets and with each other, which would otherwise produce many smaller, high velocity pieces of debris which also become concerns. The captured objects would be jettisoned into the atmosphere, relocated in 'parking' orbits, or recovered for disposition or refurbishment. The dollar value of satellites launched into space continues to grow along with the cost of insurance; having a capture capability takes a positive step towards diminishing this added cost. The effort covered is a planning step towards a flight demonstration of the satellite capture capability. Based on the requirement to capture a communication class satellite, its associated booster, or both, a preliminary system definition of a retrieval kit is defined. The objective of the flight demonstration is to demonstrate the techniques proposed to perform the mission and to obtain data on technical issues requiring an in situ space environment. The former especially includes issues such as automated image recognition techniques and control strategies that enable an unmanned vehicle to rendezvous and capture a satellite, contact dynamics between the two bodies, and the flight segment level of automation required to support the mission. A development plan for the operational retrieval capability includes analysis work, computer and ground test simulations, and finally a flight demonstration. A concept to perform a selected mission capturing a precessing communications satellite is described. Further development efforts using analytical tools and laboratory facilities are required prior to reaching the point at which a full commitment to the flight demonstration design can be made. EXTENSIONS OF SOME GUIDELINES FOR THE MECHANICAL DESIGN OF COAXIAL COMPRESSION PIN SEALS
R. S. Chambers and S. N. Burchett Mar. 1993 29 p
(Contract DE-AC04-76DP-00789)
(DE93-012385; SAND-93-0306) Avail: CASI HC A03/MF A01

Compression seals are commonly used in electronic components. Because glass has such a low fracture toughness, tensile residual stresses must be kept low to avoid cracks. A variety of compression pin seals were analyzed to identify mechanically optimal configurations when work hardened Alloy 52 conductor pins are sealed in a 304 stainless steel housing with a Kimble TM-9 glass insulator. Mechanical property tests on Alloy 52, have shown that the heat treatments encountered in a typical glass sealing cycle are capable of annealing the Alloy 52 pins, increasing ductility, and lowering the yield strength. Since most seal analyses are routinely based on unannealed Alloy 52 properties, a limited study was performed to determine the design impact of lowering the yield strength of the pins in a typical compression seal. Thermal residual stresses were computed in coaxial compression seals with annealed pins, and the results then were used to reconstruct design guidelines following the procedures employed by Miller and Burchett. Annealing was found to significantly narrow the optimal design range (as defined by a dimensionless geometric parameter). The Miller-Burchett analyses which were based on very coarse finite element meshes and a 50 ksi yield strength fortuitously predicted an overly conservative design range that is a subset of the narrow design window prevalent when the yield strength is assumed to be 34 ksi. This may not remain true for lower yield strengths. The presence of pin wetting was shown to exacerbate the glass stress state. The time is right to develop a modern and enhanced set of design guidelines which could address new material systems, three dimensional geometries, and viscoelastic effects. DOE

DURABILITY OF A CARBON SEGMENTED CIRCUMFERENTIAL SEAL FOR A LIQUID OXYGEN TURBOPUMP [EKITAI SANSO TABO PONPU YOU KABON SEGUMENTO SHIRU NO TAIKYUU SEINOU]
Masataka Kikuchi, Mamoru Oike, Masataka Nosaka, and Yoshiaki Watanabe May 1992 17 p In JAPANESE
(NAL-TR-1155; JTN-93-80440; DE93-793619) Avail: CASI HC A03/MF A01

A carbon segmented circumferential seal with Rayleigh steps, designed as a helium purge seal for the liquid oxygen turbopump of the LE-7 rocket engine, was experimentally studied to improve its durability over a wide range of operating conditions. Five combinations of sealing materials were tested for long durations using helium purged pressures from 0.3 to 0.8 MPa and speeds from 52 to 105 m/sec. Friction tests of the sealing materials were also performed to enable comparisons with the seal test results. The effects of the operating conditions and the use of carbon materials, hard coating materials on the runner, and MoS_2 lubricating films were examined to enable the tribological performance of the sealing surfaces. The test seal having a MoS_2 lubrication film sprayed on the carbon sealing surface and a runner coated with a Cr_2O_3 plasma-sprayed film demonstrated sufficient durability over a wide range of operating conditions. EXTERNAL COMBUSTION ENGINE HAVING A COMBUSTION EXPANSION CHAMBER Patent Application
Anthony W. Duva, inventor (to Navy) 23 Mar. 1993 15 p
(AD-D015761; US-Patent-Appl-SN-035862) Avail: CASI HC A03/MF A01

This patent application discloses an external combustion engine having a combustion expansion chamber. The engine includes a combustion chamber for generating a high-pressure, energized gas from a monopropellant fuel, and a cylinder for receiving the energized gas through a rotary valve to perform work on a cylinder disposed therein. A baffle plate is positioned between the combustion area and expansion area for reducing the pressure of the gas. The combustion area and expansion area are separated by a baffle plate having a flow area which is sufficiently large to eliminate the transmission of pressure pulsations from the combustion area to the expansion area while being small enough to provide for substantially complete combustion in the combustion area. The engine is particularly well suited for use in a torpedo. DTIC

HEAT REGENERATIVE EXTERNAL COMBUSTION ENGINE Patent Application
Anthony W. Duva, inventor (to Navy) 23 Mar. 1993 15 p
(AD-D015765; US-Patent-Appl-SN-035867) Avail: CASI HC A03/MF A01

It is an object of the invention to provide an external combustion expander-type engine having improved efficiency. It is another object of the invention to provide an external combustion engine in which afterburning in the exhaust channel is substantially prevented. Yet another object of the invention is to provide an external combustion engine which is less noisy than an external combustion engine of conventional design. These and other objects of the invention will become more apparent from the following description. The above objects of the invention are realized by providing a heat regenerative external combustion engine. The heat regenerative external combustion engine of the invention comprises a combustion chamber for combusting a monopropellant fuel in order to form an energized gas. The energized gas is then passed through a rotary valve to a cylinder having a reciprocating piston disposed therein. The gas is spent in moving the piston, thereby driving a drive shaft. DTIC

DUAL VALVE PLATE TWO-WAY PRESSURE RELIEF VALVE Patent Application
Robert J. Angeli, inventor (to Navy) 23 Feb. 1993 15 p
(AD-D015766; US-Patent-Appl-SN-023426) Avail: CASI HC A03/MF A01

This patent application discloses a two-way valve which includes dual valve plates to be positioned between first and second chambers having varying pressure therein, to relieve excess pressure in either chamber by permitting fluid flow from one chamber to the other. The valve includes a body portion having disposed therein dual valve plates. In the equilibrium state, the first valve plate is spring biased against the valve body in the direction of the first chamber to seal off any flow through the valve. The second valve plate is separately spring biased against the first valve plate in the direction of the second chamber, sealing off flow between the valve plates. When the pressure of the first chamber is greater than the pressure of the second chamber by a predetermined amount, the first and second valve plates move away from the valve body permitting fluid flow from the first chamber to the second chamber. When the pressure of the second chamber exerted on the second valve plate through apertures in the first valve plate is greater than the pressure of the first chamber by a predetermined amount, the second valve plate moves away from the face of the first valve plate permitting fluid flow from the second chamber to the first chamber. DTIC

VIBRATION ISOLATION MOUNT WITH LOCKING MEANS Patent Application
Stuart C. Dickinson, inventor (to Navy) 29 Mar. 1993 10 p
(AD-D015769; US-Patent-Appl-SN-037878) Avail: CASI HC A02/MF A01

A vibration isolation mount comprises a frame adapted for attachment to a support member, a spring device mounted on the fame and adapted for attachment to a protected device, the spring device being movable on the frame to permit movement of the protected device relative to the support member, and a locking mechanism for limiting movement of the spring device on the frame, thereby to limit movement of the protected device relative to the support member. DTIC

N94-10385# Department of the Navy, Washington, DC.
SELF LOCKING SET SCREW Patent Application
Michael A. Tucchio, inventor (to Navy) 3 Feb. 1993 12 p
(AD-D015774; US-Patent-Appl-SN-012837) Avail: CASI HC A03/MF A01

A threaded, locking set screw with standard outer dimensions having a threaded body, an expansion plug, and a retaining wedge. The threaded body has a tapered cavity at its bottom end. The expansion plug and retaining wedge are inserted into the cavity in the body. The base of the plug extends from the cavity, and the plug is held in place by a force fit between the wedge and a retaining slot in the body. When the set screw is tightened against a part, the plug is forced into the cavity. Because of a locking taper between the plug and the cavity, the plug exerts an outward force on the inner surface of the cavity causing the set screw body to expand radially, thus, locking the set screw in place. DTIC

OBJECT RECOGNITION IN INDUSTRIAL ENVIRONMENT BY MEANS OF TACTILE SENSOR M.S. Thesis
Michael Fainstein Oct. 1993 140 p In ENGLISH and HEBREW
(ITN-93-85200) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The practicability of using a tactile sensor for object recognition in an industrial environment was investigated. Towards this aim, two algorithms were developed for dynamic feature selection in object recognition, and a combination of statistical object recognition and template-matching was applied to the images generated by the tactile sensor. The algorithms which were developed were based on the observation that each feature can be tested and graded independently of other features on the basis of the analysis of variations statistical test. A further basic consideration was that, if two features are correlated, only one need be used for object recognition. The system's recognition success rate was about 15 percent better than that of a method based on the Karhunen-Loeve expansion. A success rate of 95-99 percent could be achieved by changing the problem to that of reducing a large set of objects to a small set of two or three candidates for a more complex and more costly recognition procedure. Problems requiring further research include the integration of an additional sensor, such as a video camera, for a second stage of object recognition; and the development of a selection procedure for identifying one out of a group of two or three candidates. AGBT ADVANCED COUNTER-ROTATING GEARBOX DETAILED DESIGN REPORT Report, Aug. 1984 - Jan. 1987
D. C. Howe, C. V. Sundt, and A. H. McKibbon Oct. 1988 164 p
(Contract NAS3-24342; RTOP 535-03-22)
(NASA-CR-180883; NAS 1.26:180883) Avail: CASI HC A08/MF A02

An Advanced Counter-Rotating (CR) Gearbox was designed and fabricated to evaluate gearbox efficiency, durability and weight characteristics for emerging propfan-powered airplanes. Component scavenge tests showed that a constant volume collector had high scavenge effectiveness, which was uneffected by added airflow. Lubrication tests showed that gearbox losses could be reduced by controlling the air/oil mixture and by directing the oil jets radially, with a slight axial component, into the sun/planet gears. Two types of systems for force-reflecting control, which enables high force-reflection gain, are presented: position-error-based force reflection and low-pass-filtered force reflection. Both of the systems are combined with shared compliance control. In the position-error-based class, the position error between the commanded and the actual position of a compliantly controlled robot is used to provide force reflection. In the low-pass-filtered force reflection class, the low-pass-filtered output of the compliance control is used to provide force reflection. The increase in force reflection gain can be more than 10-fold as compared to a conventional high-bandwidth pure force reflection system, when high compliance values are used for the compliance control.

This invention relates to an operator interface for controlling a telerobot to perform tasks in a poorly modeled environment and/or within unplanned scenarios. The telerobot control system includes a remote robot manipulator linked to an operator interface. The operator interface includes a setup terminal, simulation terminal, and execution terminal for the control of the graphics simulator and local robot actuator as well as the remote robot actuator. These terminals may be combined in a single terminal. Complex tasks are developed from sequential combinations of parameterized task primitives and recorded teleoperations, and are tested by execution on a graphics simulator and/or local robot actuator, together with adjustable time delays. The novel features of this invention include the shared and supervisory control of the remote robot manipulator via operator interface by pretested complex tasks sequences based on sequences of parameterized task primitives combined with further teleoperation and run-time binding of parameters based on task context.

COOLED SPOOL PISTON COMPRESSOR Patent
Brian G. Morris, inventor (to NASA) 24 Aug. 1993 11 p Filed 29 Dec. 1992 Supersedes N93-19331 (31 - 6, p 1550)
(NASA-Case-MSC-22020-1; US-Patent-5,238,372;
US-Patent-Appl-SN-998062; US-Patent-Class-417-393;
US-Patent-Class-417-404; Int-Patent-Class-F04B-35/00) Avail: US Patent and Trademark Office

A hydraulically powered gas compressor receives low pressure gas and outputs a high pressure gas. The housing of the compressor defines a cylinder with a center chamber having a cross-sectional area less than the cross-sectional area of a left end chamber and a right end chamber, and a spool-type piston assembly is movable within the cylinder and includes a left end closure, a right end closure, and a center body that are in sealing engagement with the respective cylinder walls as the piston reciprocates. First and second annual compression chambers are provided between the piston enclosures and center housing portion of the compressor, thereby minimizing the spacing between the core gas and a cooled surface

of the compressor. Restricted flow passageways are provided in the piston closure members and a path is provided in the central body of the piston assembly, such that hydraulic fluid flows through the piston assembly to cool the piston assembly during its operation. The compressor of the present invention may be easily adapted for a particular application, and is capable of generating high gas pressures while maintaining both the compressed gas and the compressor components within acceptable temperature limits.

DEVELOPMENT OF PASSIVE SUPERCONDUCTING BEARINGS. PHASE 3 Final Report
Dantam K. Rao 14 May 1993 100 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract SDIO84-89-C-0043)
(AD-A266050; MTI-93TR26) Avail: CASI HC A05

This report documents the development of a passive superconducting bearing that is used to levitate relatively heavy rotors. This bearing was used to levitate a 7 lb rotor and spin at speeds of up to 12,000 rpm. The success of this effort indicates that the superconducting bearings have the potential for transition from a mere laboratory curiosity to a functional bearing component in a wider range of practical applications such as cryoturbopumps, miniature cryocoolers, and magnetic refrigerators. In addition, several configurations using superconductors to support loads along a single axis were investigated. The effort was directed to identify a specific configuration that offers a very high stiffness. DTIC

A SOFT-START CIRCUIT FOR ARCJET IGNITION
John A. Hamley and John M. Sankovic Jun. 1993 24 p Presented at the 29th AIAA Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE
(RTOP 506-42-31)
(NASA-TM-106287; E-8025; NAS 1.15:106287; AIAA Paper 93-2396)
Avail: CASI HC A03/MF A01

The reduced propellant flow rates associated with high performance arcjets have placed new emphasis on electrode erosion, especially at startup. A soft-start current profile was defined which limited current overshoot during the initial 30 to 50 ms of operation, and maintained significantly lower than the nominal arc current for the first eight seconds of operation. A 2-5 kW arcjet PPU was modified to provide this current profile, and a 500 cycle test using simulated fully decomposed hydrazine was conducted to determine the electrode erosion during startup. Electrode geometry and mass flow rates were selected based on requirements for a 600 second specific impulse mission average arcjet system. The flow rate was varied throughout the test to simulate the blow down of a flight propellant system. Electrode damage was negligible at flow rates above 33 mg/s, and minor chamfering of the constrictor occurred at flow rates of 33 to 30 mg/s, corresponding to flow rates expected in the last 40 percent of the mission. Constrictor diameter remained unchanged and the thruster remained operable at the completion of the test. The soft-start current profile significantly reduced electrode damage when compared to state of the art starting techniques. Author

SENSOR ABSTRACTIONS TO SUPPORT MANY-ROBOT SYSTEMS
Douglas W. Gage Apr. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265907) Avail: CASI HC A03

The rapid evolution of micromechanical fabrication techniques and other sensor, effector, and processing technologies will soon make it possible to employ large numbers of very inexpensive autonomous mobile robots with fairly limited sensor capabilities to perform real-world missions in ground, air, space, and underwater environments. One approach to such a system is to realize desired emergent collective group behaviors with simple sensor-based reactive planners. The initial thrust of this effort has been to develop generic ensemble behaviors, such as blanket, barrier, and sweep coverage, and various deployment and recovery modes, which can address a broad spectrum of generic applications, both military and civilian. However, while different applications may require similar group behaviors, the sensor, information, and communications resources available to the participating individual robots may be very different. This paper outlines the many-robot approach to real-world problems solving and discusses the various roles that different types of sensors can play in such systems. Analysis and simulation results are presented to show how useful behavioral algorithms can be designed to make use of diverse information resources, and the area search problem is analyzed to derive both system measures of effectiveness and system design considerations. ENHANCEMENTS TO THE ENGINE DATA INTERPRETATION SYSTEM (EDIS) Final Report, 16 Apr. 1992 - 15 Apr. 1993
Martin O. Hofmann Jul. 1993 124 p
(Contract NAS8-38609)
(NASA-CR-192593; NAS 1.26:192593) Avail: CASI HC A06/MF A02

The Engine Data Interpretation System (EDIS) expert system project assists the data review personnel at NASA/MSFC in performing post-test data analysis and engine diagnosis of the Space Shuttle Main Engine (SSME). EDIS uses knowledge of the engine, its components, and simple thermodynamic principles instead of, and in addition to, heuristic rules gathered from the engine experts. EDIS reasons in cooperation with human experts, following roughly the pattern of logic exhibited by human experts. EDIS concentrates on steady-state static faults, such as small leaks, and component degradations, such as pump efficiencies. The objective of this contract was to complete the set of engine component models, integrate heuristic rules into EDIS, integrate the Power Balance Model into EDIS, and investigate modification of the qualitative reasoning mechanisms to allow 'fuzzy' value classification. The result of this contract is an operational version of EDIS. EDIS will become a module of the Post-Test Diagnostic System (PTDS) and will, in this context, provide system-level diagnostic capabilities which integrate component-specific findings provided by other modules. COMPREHENSIVE DYNAMIC ANALYSIS OF A BLADED DISK-TURBOROTOR-BEARING SYSTEM Ph.D. Thesis
Ashok Kaushal 1992 310 p
(ISBN-0-315-73646-1) Avail: Univ. Microfilms Order No. DANN73646

The dynamic behavior of a bladed disk-turborotor-bearing system is studied employing analytical, numerical, and experimental methods. The system consists of several subsystems such as turbine disk, blades, bearings, support pedestals etc. In order to completely understand the dynamic behavior of the turborotor system an appropriate model for each individual component of the system is first developed. The individual components are modeled to include various design parameters and the effect of these parameters on the vibrational behavior is studied. The vibration studies on the individual components are carried out using Rayleigh-Ritz method boundary characteristic orthogonal polynomials as assumed shape functions. The individual components are then assembled using the finite element technique. The turborotor system is studied from a system point of view and the natural frequencies and mode shapes are obtained for various rotational speeds. The results show that the natural frequencies of the system are different from those obtained by analyzing individual components, suggesting that a system approach must be adopted for proper design of a turborotor system. The amplitude of vibration and stresses due to harmonic and centrifugal loading on the blades and the disk are also obtained. The results indicate that for the turborotor speed of operation, the centrifugal loading is the major factor in determining the critical stresses in comparison to the gas forces on the blade modeled as harmonic loading. Experimental validation of the analytical model is carried out and suggestions for future work are given. Dissert. Abstr.

N94-11156 McGill Univ., Montreal (Quebec).
MECHANICAL ANALYSIS OF PARALLEL MANIPULATORS WITH SIMULATION, DESIGN, AND CONTROL APPLICATIONS Ph.D. Thesis
Ou Ma 1991 278 p
(ISBN-0-315-72013-1) Avail: Univ. Microfilms Order No. DANN72013

The kinematics and dynamics for the purposes of analysis, control, simulation, and design of general platform-type parallel manipulators are discussed. Two new methods of direct kinematics for displacement analysis are proposed. Velocity and acceleration analyses for general kinematic architectures are fully studied. Furthermore, kinematic singularities are classified based on their nature. Architecture singularities and architecture conditioning are deeply studied and incorporated into design strategies, along with design examples. Moreover, formulation singularities are also given due attention with case studies. In dynamics modeling, the method of the natural orthogonal complement is applied such that the resulting models are structurally algorithmic, computationally efficient, and numerically robust - essential properties for the implementation of more sophisticated control strategies. Efficient inverse and direct dynamics algorithms are developed based on the dynamics models in both joint space and Cartesian space. The algorithms were implemented with a general software package that is available for dynamics control and motion simulation of platform manipulators. As practical applications, the dynamics modeling and simulation of some commercial flight simulators are included. Finally, the concept of dynamic isotropy is introduced, which allows one to evaluate the motion/force performance of a manipulator with respect to control and simulation. Application strategies of this concept to some robotics problems such as design, trajectory planning, and inverse kinematics are discussed along with examples. Dissert. Abstr.

TRAJECTORY PATTERN INVERSE DYNAMICS AND CONTROL OF NONLINEAR DYNAMICS SYSTEMS WITH APPLICATION TO FLEXIBLE STRUCTURES Ph.D. Thesis
Qing Tu 1992 257 p
Avail: Univ. Microfilms Order No. DA9309990

A new approach to the study of the inherent characteristics of the nonlinear dynamics of mechanical systems, path and motion planning for systems with joint and structural flexibility, and kinematic and dynamic synthesis of such systems is presented. The investigations are based on a new method, which was referred to as the trajectory pattern method. In this method, the inherent characteristics of the nonlinear dynamics of a system is determined by selecting a trajectory pattern (i.e., the time history of motion), and examining the structure of the resulting inverse dynamics equations (models). The trajectory patterns are described in parametric form in terms of the variables of the differential equations of motion. The corresponding inverse dynamics equations can then be derived in terms of the trajectory pattern and system parameters. Each trajectory pattern produces an inverse dynamics model with a specific structure. The structure of the resulting inverse dynamics models and the fact that they can be derived in parametric form for any selected trajectory pattern, makes them ideal for investigating the inherent characteristics of the dynamics of nonlinear mechanical systems. The primary objective is the development of systematic methods for the design of a number of classes of nonlinear dynamics systems with superior dynamic characteristics; and optimal path and trajectory synthesis for tracking and point to point motions, such as for minimal vibrational excitation, minimum time with minimal residual vibration, and/or minimal sensitivity to certain system parameters and their variations. The study of the dynamic characteristics of robot manipulators includes the study of effects of the operating speed on the dynamic behavior of robot manipulators with rigid links in the presence and absence of gravitational acceleration; and the study of the effects of the payload mass, size, and end-effector holding locations. The systems considered are mechanical systems with rigid elements or with flexible joints and structures. A number of examples including computer simulation of the effectiveness of the developed method and some experimental results are presented. Dissert. Abstr.

WELDING TRITIUM AGED STAINLESS STEEL
W. R. Kanne, Jr. 1993 5 p Presented at the DOE Compatibility, Aging and Service Life Conference, Aiken, SC, 20-22 Apr. 1993
(Contract DE-AC09-89SR-18035)
(DE93-011782; WSRC-MS-93-090; CONF-9304103-5) Avail: CASI HC A01/MF A01

Stainless steels exposed to tritium become unweldable by conventional methods due to He buildup within the metal matrix. With longer service lives expected for new weapon systems, and service life extensions of older systems, methods for welding/repair on tritium-exposed material will become important. Results are reported that indicate that both solid-state resistance welding and low-heat gas metal arc overlay welding are promising methods for repair or modification of tritium-aged stainless steel. PULSED PLASMA PROCESSING FOR CONTROL OF DIESEL ENGINE EMISSIONS
G. E. Vogtlin, E. K. Freytag, J. N. Bardsley, and H. Wallman 12 Feb. 1993 8 p Presented at the Annual Automotive Development Technology Contractors' Coordination Meeting, Dearborn, MI, 2-5 Nov. 1992
(Contract W-7405-eng-48)
(DE93-011884; UCRL-JC-111555; CONF-9211101-8) Avail: CASI HC A02/MF A01

Electrical discharges can be used as an after treatment for diesel exhaust. We are presently involved in research to determine the feasibility of this process. These discharges have been shown to remove nitric oxide, sulfur dioxide, particulates, and many organic compounds. A key issue is the efficiency of this removal since it effects both capital and operating costs. These discharges must be of short duration, less than one microsecond, to avoid energy losses due to heating of bulk gas molecules. The voltage must be kept below the voltage breakdown limit where ion heating creates an arc discharge. The basic process is the acceleration of electrons which then collide with gas molecules to form radicals such as O and OH. These radicals then react with and eliminate pollutants. Two basic electrode geometries are used to generate these discharges. The barrier discharge is when one or both of the electrodes is insulated and the pulse length is limited by charging of the insulator. This discharge must be driven by alternating current to permit alternating charging of the insulator. The other geometry is when one electrode has a peak voltage stress five or more times the average stress. We have been investigating the high stress geometry which uses a small wire inside a pipe. The principal experimental apparatus utilized by this effort uses a closed loop gas system. This system permits the production of various gas combinations prior to testing. Analysis can be conducted during or after these tests. The recirculated gas can be heated up to 400 F. This system can measure the energy used and the pollutant removal to determine efficiency. Our primary goal is the simultaneous removal of nitric oxide and particulates typical of diesel exhaust. This is expected to be accomplished in one or more metal tubes no larger than two inches in diameter and 36 inches long. DOE

A PORTABLE CONTROLLER FOR UNMANNED GROUND VEHICLES
A. Y. Umeda, T. W. Hughes, A. H. Koyamatusu, B. N. Nobunaga, and K. K. Yamada Mar. 1993 6 p
(AD-A264963) Avail: CASI HC A02/MF A01

The portable remote vehicle controller (PRVC), recently developed at the Naval Command, Control and Ocean Surveillance Center's Research, Development, Test and Evaluation Division (NRaD) Detachment, Kailua, Hawaii, provides a lightweight, compact, teleoperator control station that allows remote, high speed control of unmanned ground vehicles (UGV). This ruggedized UGV operator control unit is configurable to work in any operating environment. Test drivers rated PRVC's ergonomically designed steering, brake and throttle controls superior to other driving configurations. All functional vehicle controls are easily accessible and can be manipulated by feel-without the need to look at physical buttons or levers. Graphic overlays displayed on the video image inform the UGV operator of critical system conditions and obviate the need to concentrate on other visual displays. Fiber optic data communications to the UGV, and RF audio communication to the military networks are fully supported by the PRVC. DTIC

LIFE-CYCLE COST ANALYSIS OF CONVENTIONAL AND FUEL CELL/BATTERY POWERED URBAN PASSENGER VEHICLES
30 Nov. 1992 248 p
(Contract DE-AC02-91CH-10491)
(DE93-010770; DOE/CH-10491/1) Avail: CASI HC A11/MF A03

This Final Report summarizes the work on the life cycle cost (LCC) analysis of conventional and fuel cell/battery powered urban passenger vehicles. The purpose of the work is to support the Division in making sound economic comparisons between conventional and fuel cell/battery powered buses, passenger vans, and cars for strategic analysis of programmatic R&D goals. The LCC analysis can indicate whether paying a relatively high initial capital cost for advanced technology with low operating and/or environmental costs is advantageous over paying a lower initial cost for conventional technology with higher operating and/or environmental costs. While minimizing life cycle cost is an important consideration, it does not always result in technology penetration in the marketplace. The LCC analysis model developed under this contract facilitates consideration of all perspectives. Over 100 studies have been acquired and analyzed for their applicability. Drawing on prior work by JPL and Los Alamos National Laboratory as primary sources, specific analytical relationships and cost/performance data relevant to fuel cell/battery and internal combustion engine (ICE) powered vehicles were selected for development of an LCC analysis model. The completed LCC model is structured around twelve integrated modules. Comparative analysis is made between conventional gasoline and diesel vehicles and fuel cell/battery vehicles using either phosphoric acid fuel cells or proton-exchange membrane fuel cells. In all, seven base vehicle configuration cases with a total of 21 vehicle class/powertrain/fuel combinations are analyzed. The LCC model represents a significant advance in comparative economic analysis of conventional and fuel cell/battery powered vehicle technologies embodying several unique features which were not included in prior models. DOE

INSTANTANEOUS ENGINE FRICTIONAL TORQUE: ITS COMPONENTS AND PISTON ASSEMBLY FRICTION
Fred A. Nichols, ed. and N. A. Henein (Wayne State Univ., Detroit, MI.) May 1992 197 p
(Contract W-31-109-eng-38)
(DE93-011639; ANL/OTM/CR-1) Avail: CASI HC A09/MF A03

The overall goal of this report is to document the work done to determine the instantaneous frictional torque of an internal combustion engine by using a new approach known as the P-(omega) method developed at Wayne State University. The emphasis has been to improve the accuracy of the method, and apply it to both diesel and gasoline engines under different operating conditions. Also work included an investigation to determine the effect of using advanced materials and techniques to coat the piston rings on the instantaneous engine frictional torque and the piston assembly friction. The errors in measuring the angular velocity, omega, have been determined and found to be caused by variations in the divisions within one encoder, encoder-to-encoder variations, misalignment within the encoder itself, and misalignment between the encoder and crankshaft. The errors in measuring the cylinder gas pressure, P, have been determined and found to be caused by transducer-to-transducer variations, zero drift, thermal stresses and lack of linearity. The ability of the (P-(omega)) method in determining the frictional torque of many engine components has been demonstrated. These components include valve train, fuel injection pump with and without fuel injection, and piston with and without different ring combinations. The emphasis in this part of the research program has been on the piston-ring assembly friction. The effects of load and other operating variables on IFT have been determined. The motoring test, which is widely used in industry to measure engine friction has been found to be inaccurate. The errors have been determined at different loads. DOE

PROPERTIES OF INTERFACIAL TRIBO-FILMS Final Report, 15 Mar. 1992 - 28 Feb. 1993
D. D. Makel and D. Kuhlmann-Wilsdorf Jun. 1993 239 p
(Contract N00014-92-J-1505)
(AD-A265591; UVA/525755/MSE93/101) Avail: CASI HC A11/MF A03

Research has been conducted on the properties of interfacial films of the kind formed in the course of sliding wear, named 'tribo-films.' Using specialized instrumentation, in particular the so-called Hoop Apparatus and a Bridgman-Anvil Device, we have found many new insights into the fundamental mechanisms responsible for the phenomena observed during sliding. In particular, advances have been made in the following areas: (1) the understanding of lubrication through adsorbed films; (2) the fundamental understanding of stick-slip; (3) the deformation mechanisms at high strains, pertinent to tribo-films and sub-surface regions; (4) micromechanisms of MoS2 lubrication; (5) understanding the implications of various material properties for possible solid lubricants; and (6) the formation of amorphous tribo-material by high strains. The results from this contract have been documented in 14 refereed publications. DTIC

RESEARCH DEVELOPMENT AND DEMONSTRATION OF A FUEL CELL/BATTERY POWERED BUS SYSTEM
S. Romano and R. Wimmer Feb. 1993 218 p
(Contract DE-AC02-87NV-10649)
(DE93-013778; DOE/NV-10649/T1) Avail: CASI HC A10/MF A03

During 1992, the design of the three test bed buses evolved. Georgetown participated in all the working meetings and the preliminary design review of the Test Bed Bus (TBB). Throughout the Year, Georgetown provided input on system design and integration issues, transit industry requirements, and bus performance. GU also attended technical seminars, presenting papers at two. The computer simulation 'HYBRID', developed by Georgetown, was used to assess performance of different bus designs and system control algorithms. GU also modified the simulation to be more flexible and allow easier evaluation of designs. Georgetown had Exhibitgroup design and construct, to our specifications, a fuel cell bus display with a 1/10 scale model of the TBB for use at trade shows and exhibits. Energy Partners of West Palm Beach, Florida completed their subcontract for the engineering design study of a hydrogen fueled, fuel-cell-powered multi-passenger vehicle. Georgetown performed a study to determine the size of the US bus fleet and expected new bus deliveries over the next 10 years. Trojan Battery Company of Santa Fe Springs, California conducted a study to determine the specific design characteristics required of a lead acid battery to meet the special requirements posed by hybrid vehicle operation. Finally, GU assisted the prime contractor with the design of the system controller and its control algorithms. DOE

BAYESIAN RELIABILITY ANALYSIS WITH IMPRECISE PRIOR PROBABILITIES
F. P. A. Coolen and M. J. Newby Dec. 1992 31 p
(MEMO-COSOR-92-50; ETN-93-94329) Copyright Avail: CASI HC A03/MF A01

An extension of the standard Bayesian approach based on the theory of imprecise probabilities and intervals of measures is developed. The Bayesian framework for statistical inference offers the possibility of taking expert opinions into account. It is attractive in practical problems concerning reliability of technical systems. Probability is the only language in which uncertainty can be consistently expressed, and this requires the use of prior distributions for reporting expert opinions. It is shown that it is necessary to take the nature of experts knowledge into account. The application of this approach in reliability theory is outlined. ESA

(DE93-011560; IS-M-741; CONF-920799-7) Avail: CASI HC A02/MF A01

The phase-screen approximation (PSA) can be used to model interaction of ultrasound with rough surfaces if the height variation is small and correlation length is large relative to wavelength. Material noise is enhanced for early times and decreased for late times. PSA can calculate ultrasound transmission through random rough surfaces; as a numerical method, it will be most appropriate for complicated problems such as rough curved surfaces, where the Boundary Integral Equation is too time-consuming. PSA can serve as a starting point for analyzing the physics of transmission through rough surfaces. However, it needs corrections to the amplitude of the transmitted wave. Nonetheless, it can serve as the basic engineering model for the effects of surface roughness on ultrasonic inspections. DOE

(DE93-753188; JAERI-M-92-086) Avail: CASI HC A03

Microhardness and SP tests were conducted to improve the reliability of ductile-brittle transition temperature (DBTT) shift evaluation caused by aging (thermal aging, neutron irradiation, cold rolling) using several model alloys (Fe-0.15C alloys and 2 1/4 Cr-1Mo steels). Although evaluation of DBTT by the SP test was overall good, intergranular brittleness could not be detected by SP DBTT measurement only. By combining other measurements like fractographic observation, however, material degradation can be evaluated more properly. DOE

POTENTIAL TECHNIQUES FOR NON-DESTRUCTIVE EVALUATION OF CABLE MATERIALS
Kenneth T. Gillen, Roger L. Clough, Bengt Mattson (Royal Inst. of Tech., Stockholm, Sweden.), Bengt Stenberg (Royal Inst. of Tech., Stockholm, Sweden.), and Erik Oestman (Skega A.B., Ersmark, Sweden.) 1993 13 p Presented at the EPRI Workshop on Power Plant Cable Condition Monitoring, San Francisco, CA, 9-11 Feb. 1993
(Contract DE-AC04-76DP-00789)
(DE93-008350; SAND-93-0308C; CONF-930254-3) Avail: CASI HC A03/MF A01

This paper describes the connection between mechanical degradation of common cable materials, in radiation and elevated temperature environments, and density increases caused by the oxidation which leads to this degradation. Two techniques based on density changes are suggested as potential non-destructive evaluation (NDE) procedures which may be applicable to monitoring the mechanical condition of cable materials in power plant environments. The first technique is direct measurement of density changes, via a density gradient column, using small shavings removed from the surface of cable jackets at selected locations. The second technique is computed X-ray tomography, utilizing a portable scanning device. DOE

Oak Ridge National Laboratory (ORNL) is one of the nation's largest and most widely diversified federal multipurpose research and development centers. The Laboratory is operated by Martin Marietta Energy Systems Inc. for the U.S. DOE. Its mission embraces non-nuclear as well as nuclear energy development together with a wide range of supporting research in engineering, physical sciences, and life sciences, as well as social sciences and economics. The Laboratory's program is dominated by four major areas of development that are approximately equal in size: nuclear (fission) energy development; basic physical sciences research; biomedical and environmental; and magnetic fusion energy development. This document outlines ORNL's quality assurance (QA) program in response to the ten criteria of DOE order 5700.6C. Guidance for implementation comes both from Attachment 1 of 5700.6C and DOE-ER-STD-6001-92. The bases for the program, integration of DOE orders, program architecture, assessment activities, and financial restraints are discussed. DOE

PAYLOAD SENSITIVITY IN COUPLED BENDING AND TORSIONAL VIBRATIONS IN FLEXIBLE BEAMS
M. Vajta Nov. 1992 135 p
(MEMO-1102; ETN-93-94315) Avail: CASI HC A07/MF A02

The sensitivity of coupled bending and torsional vibrations in flexible robot arms to the payload parameters is analyzed. The coupling is usually disregarded but it is ultimately present due to the asymmetricity of a realistic payload. The coupling is shown to modify the system dynamics, most dominantly in mid-frequency range. The kinematic equations are given assuming an Euler Bernoulli model with Voigt type of internal damping and with an asymmetric tip body. Different damping coefficients in bending and in torsional vibrations are applied. The exact frequency response in the frequency domain is given. Based on a frequency function, a sensitivity analysis regarding the payload parameters is provided. A computer package was developed to calculate the frequency responses, the sensitivity functions, and their pole zero configurations. Properties of the sensitivity functions and of their pole zero configurations are given. ESA

HYDROSTATIC TESTING OF THICK LAMINATED COMPOSITE CYLINDERS FOR PERFORMANCE MODEL VALIDATION
H. W. Blake and J. M. Starbuck Mar. 1993 225 p
(Contract DE-AC05-84OR-21400)
(DE93-012728; ORNL/ATD-67) Avail: CASI HC A10/MF A03

This report details the design, fabrication, and testing of four S-GLASS cylinders and an all circ-wound graphite cylinder. The results of an extensive parametric design study are presented. The study formed the foundation for the test article constructions. Included are the details of the cylinder constructions, the design calculations for stress and buckling, and the cylinder failure predictions. Analytical results are presented for both closed-form elasticity solutions and finite element methods. The test data and observations from the five hydrotests are summarized and correlated with the analytical results. Also provided are the details of a performance model for thick composites in compression, validated by the results of the experimental/analytical correlation. The predicted first-ply failure pressures from the performance model were within 10% of the experimentally measured pressures with the exception of the 2:1 hoop:axial ply ratio S-GLASS cylinder. The performance of this cylinder was underpredicted by 25%. DOE

POTENTIAL CHANGE IN FLAW GEOMETRY DURING PRESSURIZED-THERMAL-SHOCK TRANSIENTS
D. K. M. Shum, J. W. Bryson, J. G. Merkle, J. Keeney-Walker, T. L. Dickson, and B. R. Bass 1993 42 p Presented at the Pressure Vessel and Piping Conference, Denver, CO, 25-29 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE93-009709; CONF-930702-12) Avail: CASI HC A03/MF A01

This study presents preliminary estimates on the potential change in flaw geometry of an initially shallow, axially oriented, inner-surface finite-length flaw in a PWR-RPV during the course of a postulated PTS transient. Specifically, the question being addressed is whether a shallow, axially oriented, finite-length surface flaw would tend to elongate in the axial direction and/or deepen into the wall of the vessel during the transient. In the first part of the study, estimates are obtained based on the assumptions of linear-elastic material response. The thermo-elastic properties of the cladding and base material are explicitly considered. The flaw geometry corresponds to a family of modified-elliptical flaws characterized by the flaw's half-length to maximum depth (aspect ratio). Requirements for numerical convergence of the finite element results are examined. In the second part of the study, the sensitivity of the numerical results and conclusions obtained in the first part of the study to the following three analysis assumptions are evaluated: (1) Reference flaw geometry along the entire crack front and especially within the cladding region; (2) Linear-elastic versus elastic-plastic description of material response; and (3) Base-material-only vs bi-material cladding-base vessel-model assumption. DOE

COMPUTATIONAL PROCEDURES FOR DETERMINING PARAMETERS IN RAMBERG-OSGOOD ELASTOPLASTIC MODEL BASED ON MODULUS AND DAMPING VERSUS STRAIN
Tzou-Shin Ueng and Jian-Chu Chen Jul. 1992 18 p
(Contract W-7405-eng-48)
(DE93-013309; UCRL-ID-111487) Avail: CASI HC A03/MF A01

A computer code, RAMBO, is developed for obtaining the values of parameters in the Ramberg-Osgood elastoplastic model based on data of shear modulus and damping ratio at various shear strains. The basis and procedures for finding the parameters for the best fit of the data or relations defining modulus and damping ratios versus shear strain are given in this report. The Ramberg-Osgood relationship is rearranged so that the results can best fit data of both modulus and damping ratio. Constraints of data in the model are also discussed. DOE

MATERIAL CHARACTERIZATION AND MODELING WITH SHEAROGRAPHY Final Report
Gary L. Workman and Virginia Callahan 7 Jun. 1993 66 p
(Contract NAS8-38609)
(NASA-CR-192576; NAS 1.26:192576) Avail: CASI HC A04/MF A01

Shearography has emerged as a useful technique for nondestructible evaluation and materials characterization of aerospace materials. A suitable candidate for the technique is to determine the response of debonds on foam-metal interfaces such as the TPS system on the External Tank. The main thrust is to develop a model which allows valid interpretation of shearographic information on TPS type systems. Confirmation of the model with shearographic data will be performed. (NASA-TM-105603; E-6240; NAS 1.15:105603) Avail: CASI HC A03/MF A01

This paper summarizes a methodology developed at NASA Lewis Research Center which computationally simulates the structural, material, and load uncertainties associated with Space Shuttle Main Engine (SSME) components. The methodology was applied to evaluate the scatter in static, buckling, dynamic, fatigue, and damage behavior of the SSME turbo pump blade. Also calculated are the probability densities of typical critical blade responses, such as effective stress, natural frequency, damage initiation, most probable damage path, etc. Risk assessments were performed for different failure modes, and the effect of material degradation on the fatigue and damage behaviors of a blade were calculated using a multi-factor interaction equation. Failure probabilities for different fatigue cycles were computed and the uncertainties associated with damage initiation and damage propagation due to different load cycle were quantified. Evaluations on the effects of mistuned blades on a rotor were made; uncertainties in the excitation frequency were found to significantly amplify the blade responses of a mistuned rotor. The effects of the number of blades on a rotor were studied. The autocorrelation function of displacements and the probability density function of the first passage time for deterministic and random barriers for structures subjected to random processes also were computed. A brief discussion was included on the future direction of probabilistic structural analysis. Author (revised)

METHOD OF RECERTIFYING A LOADED BEARING MEMBER USING A PHASE POINT Patent
Joseph S. Heyman, inventor (to NASA) 17 Aug. 1993 13 p Filed 19 Jun. 1991 Supersedes N92-11384 (29 - 2, p 249)
(NASA-Case-LAR-14741-1; US-Patent-5,237,516; US-Patent-Appl-SN-720153; US-Patent-Class-364-508; US-Patent-Class-73-761; US-Patent-Class-73-862.59; US-Patent-Class-364-571.03; Int-Patent-Class-G01H-1/00; Int-Patent-Class-G01N-29/16) Avail: US Patent and Trademark Office

A method of recertifying a load on a bearing member using a pulsed phase locked loop (P2L2) system is disclosed. A first tone burst signal with a corresponding first phase signal is generated in the bearing member in a first load condition. The sample/hold of the P2L2 is adjusted to a determined phase point on the first phase signal and then the P2L2 is locked at this phase period to determine a first load measurement. Next, the phase sample point is correlated with a corresponding position, w, on the first tone burst signal. A second tone burst with a corresponding second phase signal is then generated at some later time in the bearing member in a second load condition. The sample/hold is adjusted to the sample/hold phase point as before and then the output frequency of the P2L2 is adjusted until the sample/hold is positioned at the previously determined phase point corresponding to position w on the second tone burst signal. The P2L2 is then locked at this phase point to determine a frequency indicative of the load of the second loading condition.

ELASTIC PLASTIC FRACTURE MECHANICS METHODOLOGY FOR SURFACE CRACKS Semiannual Report No. 2
Hugo A. Ernst, D. W. Boatwright, W. J. Curtin, and D. M. Lambert Aug. 1993 114 p
(Grant NAG8-243)
(NASA-CR-194129; NAS 1.26:194129) Avail: CASI HC A06/MF A02

The Elastic Plastic Fracture Mechanics (EPFM) Methodology has evolved significantly in the last several years. Nevertheless, some of these concepts need to be extended further before the whole methodology can be safely applied to structural parts. Specifically, there is a need to include the effect of constraint in the characterization of material resistance to crack growth and also to extend these methods to the case of 3D defects. As a consequence, this project was started as a 36 month research program with the general objective of developing an EPFM methodology to assess the structural reliability of pressure vessels and other parts of interest to NASA containing defects. This report covers a computer modelling algorithm used to simulate the growth of a semi-elliptical surface crack; the presentation of a finite element investigation that compared the theoretical (HRR) stress field to that produced by elastic and elastic-plastic models; and experimental efforts to characterize three dimensional aspects of fracture present in 'two dimensional', or planar configuration specimens. FATIGUE-LIFE BEHAVIOR AND MATRIX FATIGUE CRACK SPACING IN UNNOTCHED SCS-6/TIMETAL 21S METAL MATRIX COMPOSITES
G. T. Ward, D. J. Herrmann, and B. M. Hillberry Jul. 1993 27 p
(Grant NAG1-1316; RTOP 763-23-45-85)
(NASA-CR-191467; NAS 1.26:191467) Avail: CASI HC A03/MF A01

Fatigue tests of the SCS-6/Timetal 21S composite system were performed to characterize the fatigue behavior for unnotched conditions. The stress-life behavior of the unnotched (9/90)2s laminates was investigated for stress ratios of R = 0.1 and R = 0.3. The occurrence of matrix cracking was also examined in these specimens. This revealed multiple matrix crack initiation sites throughout the composite, as well as evenly spaced surface cracks along the length of the specimens. No difference in fatigue lives were observed for stress ratios of R = 0.1 and R = 0.3 when compared on a stress range basis. The unnotched

SCS-6/Timetal 21S composites had shorter fatigue lives than the SCS-6/Ti-15-3 composites, however the neat Timetal 21S matrix material had a longer fatigue life than the neat Ti-15-3. Author (revised)

COMPUTATIONAL SIMULATION OF HOT COMPOSITE STRUCTURES
C. C. Chamis, P. L. N. Murthy, and S. N. Singhal (Sverdrup Technology, Inc., Brook Park, OH.) Sep. 1993 16 p Presented at the 10th Biennial Conference on Reliability, Stress Analysis and Failure Prevention, Albuquerque, NM, 19-22 Sep. 1993; sponsored by ASME
(RTOP 510-01-50)
(NASA-TM-106200; E-7908; NAS 1.15:106200) Avail: CASI HC A03/MF A01

Computational procedures are described to simulate the thermal and mechanical behavior of high temperature metal matrix composites (HT-MMC) in the following three broad areas: (1) Behavior of HT-MMC's from micromechanics to laminate via Metal Matrix Composite Analyzer (METCAN), (2) tailoring of HT-MMC behavior for optimum specific performance via Metal Matrix Laminate Tailoring (MMLT), and (3) HT-MMC structural response for hot structural components via High Temperature Composite Analyzer (HITCAN). Representative results from each area are presented to illustrate the effectiveness of computational simulation procedures. The sample case results show that METCAN can be used to simulate material behavior such as strength, stress-strain response, and cyclic life in HTMMC's; MMLT can be used to tailor the fabrication process for optimum performance such as that for in-service load carrying capacity of HT-MMC's; and HITCAN can be used to evaluate static fracture and fatigue life of hot pressurized metal matrix composite rings. IMPERFECTION SENSITIVITY OF THE BRAZIER EFFECT FOR ORTHOTROPIC CYLINDRICAL SHELLS
Menahem Baruch, Johann Arbocz, and G. Q. Zhang 1990 24 p
(LR-687; ETN-93-94415) Avail: NTIS HC A03/MF A01

The sensitivity to imperfections of the Brazier effect for orthotropic circular shells is investigated. Cylindrical tubes are subjected to a bending moment loose stability for a certain value of the moment and buckle. Using an elegant (but somewhat approximate) approach, Brazier determined the limit moment for infinitely long circular tubes subjected to pure bending. It is shown that the limit point of the external critical bending moment of an orthotropic cylindrical tube is sensitive but not very sensitive to initial imperfections. Both the critical moment and the critical longitudinal stresses are reduced by the initial imperfections. ESA

NONLINEAR RESPONSE OF A CLAMPED-CLAMPED BEAM WITH INTERNAL RESONANCE UNDER SINUSOIDAL EXCITATION Ph.D. Thesis
Abdul-Hafiz Ahmed Afaneh 1992 219 p
Avail: Univ. Microfilms Order No. DA9310614

The nonlinear response characteristics of a clamped-clamped beam is investigated analytically, numerically, and experimentally. The beam is under an initial static axial load and subjected to a harmonic excitation of its support. Two ranges of the axial load are considered. These are below (the beam is initially straight) and above Euler buckling load (the beam is initially buckled). Hamilton's principle is used to derive a fourth order partial differential equation of motion which is descritized and reduced to a set of second order ordinary differential equations by applying Galerkin's method. Under certain values of the static load, the normal modes are nonlinearly coupled and this coupling results in a fourth order internal resonance condition between the first three modes when the beam is initially straight. Second and third order internal resonance conditions occur between the first two modes for the case of initially buckled beam. The multiple scales method showed the significant effects of these internal resonance conditions on the system behavior. In the straight beam case, the third mode which is externally excited transfers energy to the first two modes within a small range of internal detuning. Outside this region, the response is governed by a unimodal response of the third mode. In the neighborhood of 1:1 internal resonance, it is found that within the region of two mode interaction, the solution is either stationary or nonstationary depending on the excitation level and system parameters. Saturation and jump phenomena are found to take place in the case of two mode interaction with 2:1 internal resonance. Numerical simulation and experimental testing confirmed these predictions and revealed the occurrence of multifurcation, snap-through (escaping from one well to the other in an irregular manner), and chaotic motion. Dissert. Abstr.

AN ELECTRO-OPTICAL SYSTEM FOR THE MEASUREMENT OF STRAINS Ph.D. Thesis
Gopalakrishna K. Bhat 1992 240 p
Avail: Univ. Microfilms Order No. DA9311927

Optical techniques for whole field displacement measurement, such as moire, holography, and speckle interferometry are attractive within the engineering industry in a variety of areas ranging from nondestructive testing and quality control to research and development. However, these techniques were restricted to research laboratories because of the specialized equipment and the laborious photographic process needed to record the images, and the skillful personnel needed to interpret the images. The major objective was to develop the basic principles of operation of an electro-optical system which can be used for the stress analysis of structures in the field. This objective was accomplished by means of three stages. The first stage was interfacing optical systems with the digital imaging system for the real time observation of whole field displacement patterns. Images of test objects are recorded using a TV camera (instead of a photographic film) and processed using a digital image processing system. The second stage was development of digital techniques for the analysis of interferometric fringes. Two dimensional Fourier transform techniques (spatial heterodyning and local heterodyning are developed to obtain the displacement and strain fields from the interferometric fringes. Techniques to minimize the errors introduced by the sharp object boundaries and to compute the strain field without obtaining the displacement field are also introduced. The third stage was application to study the feasibility of the system. The electro-optical system is employed to measure displacements and strains: under static and dynamic conditions, at normal and elevated temperatures and at the macro and micro levels. The applications include: measurement of strains in a disk subjected diametral compression, strain measurement at high temperatures, modal analysis of turbine blades, contact stress analysis; and measurement of the displacement field in the vicinity of a crack tip. NASTRAN MODELING OF FLIGHT TEST COMPONENTS FOR UH-60A AIRLOADS PROGRAM TEST CONFIGURATION Final Report
Florentino R. Idosor and Frieder Seible Feb. 1993 173 p Original contains color illustrations
(Contract NCC2-712)
(NASA-CR-193614; NAS 1.26:193614; SSRP-93/03) Avail: CASI HC A08/MF A02; 9 functional color pages

Based upon the recommendations of the UH-60A Airloads Program Review Committee, work towards a NASTRAN remodeling effort has been conducted. This effort modeled and added the necessary structural/mass components to the existing UH-60A baseline NASTRAN model to reflect the addition of flight test components currently in place on the UH-60A Airloads Program Test Configuration used in NASA-Ames Research Center's Modern Technology Rotor Airloads Program. These components include necessary flight hardware such as instrument booms, movable ballast cart, equipment mounting racks, etc. Recent modeling revisions have also been included in the analyses to reflect the inclusion of new and updated primary and secondary structural components (i.e., tail rotor shaft service cover, tail rotor pylon) and improvements to the existing finite element mesh (i.e., revisions of material property estimates). Mode frequency and shape results have shown that components such as the Trimmable Ballast System baseplate and its respective payload ballast have caused a significant frequency change in a limited number of modes while only small percent changes in mode frequency are brought about with the addition of the other MTRAP flight components. With the addition of the MTRAP flight components, update of the primary and secondary structural model, and imposition of the final MTRAP weight distribution, modal results are computed representative of the 'best' model presently available. MULTILEVEL COMPUTER-AIDED OPTIMUM DESIGN OF STRUCTURAL SYSTEMS USING MULTIPLE BASIS VECTORS Ph.D. Thesis
Kang-Seon Seomun 1992 312 p
Avail: Univ. Microfilms Order No. DA9310868

A new alternative multilevel structural optimization method using multiple basis vectors for each substructure is presented. The system level design task is formulated using multiple design space basis vectors for each substructure and the corresponding participation coefficients (system level design variables). In the system level design problem the total structural weight is minimized, subject to the system level constraints, namely static displacement limitations and natural frequency constraints. At the end of a system level optimization stage, the weight of each substructure is evaluated and used to establish an updated upper bound weight cap constraint for each upcoming substructure optimization procedure. At the subsystem level the structure is decomposed into a number of small substructures each one of which contains multiple design space basis vectors. A buffer (slack) variable is selected as the objective function for each substructure. Stress and member buckling constraints are incorporated at the subsystem level. The design modification problem at the subsystem level is formulated in a manner such that maximization of the buffer variable drives the substructure design vector away; from all of the constraints except the side constraints. After completing the subsystem level optimization task, the final values of buffer variables, local behavior constraints, and local design variables are obtained and used to evaluate lower limit values for the upcoming system level design variables. At both the system level and the subsystem level, design modification is carried out by solving a sequence of explicit approximate problems. The new alternative multilevel method which introduces multiple basis vectors for each substructure leads to greater flexibility when constructing and solving design optimization models for large structural systems. Dissert. Abstr.

FRACTURE MECHANICS AND FULL SCALE PIPE BREAK TESTING FOR THE DEPARTMENT OF ENVIRONMENT'S NEW PRODUCTION REACTOR-HEAVY WATER REACTOR
A. B. Poole 1992 33 p Presented at the 24th National American Society for Testing and Materials Symposium on Fracture Mechanics, Gatlinburg, TN, 30 Jun. - 2 Jul. 1992
(Contract DE-AC05-84OR-21400)
(DE93-005428; CONF-920672-4) Avail: CASI HC A03/MF A01 (US Sales Only)

Oak Ridge National Laboratory (ORNL) is completing a major task for the Department of Energy (DOE) in the demonstration that the primary piping of the New Production Heavy Water Reactor (NPR-HWR), with its relatively moderate temperature and pressure, should not suffer an instantaneous Double-Ended-Guillotine-Break (DEGB) under design basis loadings and conditions. The growth of possible small preexisting defects in the piping wall was estimated over a plant life of 60 years. This worst case flaw was then evaluated using fracture mechanics methods. J estimation methods and tearing instability approximations used in this analysis are discussed in this paper. It was established that this worst case flaw would increase in size by at least 14 times before pipe instability during an earthquake would even begin to be possible. The fatigue crack growth analysis is discussed in this paper. DOE

FAILURE PREDICTION OF THIN BERYLLIUM SHEETS USED IN SPACECRAFT STRUCTURES Final Technical Report, 1 Jul. 1990 - 30 Jun. 1991
Paul N. Roschke, Edward Mascorro, Photios Papados, and Oscar R. Serna 1991 260 p
(Grant NAG9-280)
(NASA-CR-194164; NAS 1.26:194164) Avail: CASI HC A12/MF A03

The primary objective of this study is to develop a method for prediction of failure of thin beryllium sheets that undergo complex states of stress. Major components of the research include experimental evaluation of strength parameters for cross-rolled beryllium sheet, application of the Tsai-Wu failure criterion to plate bending problems, development of a high order failure criterion, application of the new criterion to a variety of structures, and incorporation of both failure criteria into a finite element code. A Tsai-Wu failure model for SR-200 sheet material is developed from available tensile data, experiments carried out by NASA on two circular plates, and compression and off-axis experiments performed in this study. The failure surface obtained from the resulting criterion forms an ellipsoid. By supplementing experimental data used in the the two-dimensional criterion and modifying previously suggested failure criteria, a multi-dimensional failure surface is proposed for thin beryllium structures. The new criterion for orthotropic material is represented by a failure surface in six-dimensional stress space. In order to determine coefficients of the governing equation, a number of uniaxial, biaxial, and triaxial experiments are required. Details of these experiments and a complementary ultrasonic investigation are described in detail. Finally, validity of the criterion and newly determined mechanical properties is established through experiments on structures composed of SR200 sheet material. These experiments include a plate-plug arrangement under a complex state of stress and a series of plates with an out-of-plane central point load. Both criteria have been incorporated into a general purpose finite element analysis code. Numerical simulation incrementally applied loads to a structural component that is being designed and checks each nodal point in the model for exceedance of a failure criterion. If stresses at all locations do not exceed the failure criterion, the load is increased and the process is repeated. Failure results for the plate-plug and clamped plate tests are accurate to within 2 percent. Author (revised)

UNDERSTANDING CRACKING FAILURES OF COATINGS: A FRACTURE MECHANICS APPROACH Ph.D. Thesis
Sung-Ryong Kim 1993 223 p
Avail: Univ. Microfilms Order No. DA9311236

A fracture mechanics analysis of coating (paint) cracking was developed. A strain energy release rate (G(sub c)) expression due to the formation of a new crack in a coating was derived for bending and tension loadings in terms of the moduli, thicknesses, Poisson's ratios, load, residual strain, etc. Four-point bending and instrumented impact tests were used to determine the in-situ fracture toughness of coatings as functions of increasing baking (drying) time. The system used was a thin coating layer on a thick substrate layer. The substrates included steel, aluminum, polycarbonate, acrylonitrile-butadiene-styrene (ABS), and Noryl. The coatings included newly developed automotive paints. The four-point bending configuration promoted nice transversed multiple coating cracks on both steel and polymeric substrates. The crosslinked type automotive coatings on steel substrates showed big cracks without microcracks. When theoretical predictions for energy release rate were compared to experimental data for coating/steel substrate samples with multiple cracking, the agreement was good. Crosslinked type coatings on polymeric substrates showed more cracks than theory predicted and the G(sub c)'s were high. Solvent evaporation type coatings on polymeric substrates showed clean multiple cracking and the G(sub c)'s were higher than those obtained by tension analysis of tension experiments with the same substrates. All the polymeric samples showed surface embrittlement after long baking times using four-point bending tests. The most apparent surface embrittlement was observed in the acrylonitrile-butadiene-styrene (ABS) substrate system. The impact properties of coatings as a function of baking time were also investigated. These experiments were performed using an instrumented impact tester. There was a rapid decrease in G(sub c) at short baking times and convergence to a constant value at long baking times. The surface embrittlement conditions and an embrittlement toughness were found upon impact loading. This analysis provides a basis for a quantitative approach to measuring coating toughness. Measuring toughness can be used to develop new coating systems. With these results the cracking behavior of baked coatings can be used to predict the durability or long time cracking behavior of those coatings. Dissert. Abstr.

The artificial neural networks (ANN) methodology is an outgrowth of research in artificial intelligence. In this study, the feed-forward network model that was proposed by Rumelhart, Hinton, and Williams was applied to the mapping of functions that are encountered in structural mechanics problems. Several different network configurations were chosen to train the available data for problems in materials characterization and structural analysis of plates and shells. By using the recall process, the accuracy of these trained networks was assessed. Author (revised)

A STUDY OF STRENGTH EVALUATIONS OF EDNI/EDCu/NARloy-Z BONDED JOINTS
J. B. Min and K. L. Spanyer Jul. 1993 27 p
(NASA-TM-108418; NAS 1.15:108418) Avail: CASI HC A03/MF A01

Dissimilar material interfaces can be found in many materials and structural bonds such as composite materials, welded parts, inclusion in matrix, bond between metallic and ceramic materials, and so forth. One of such structural bonds can be seen in the main combustion chamber (MCC) of the Space Shuttle Main Engine (SSME). In this study, from a practical sense, the primary concern is to understand the systems response of EDNi/EDCu/NARloy-Z bonded joints using stress values approximated by the finite element method to determine an influence of the variation of structural bond parameters on the bonded joints, and consequently main combustion chamber of the Space Shuttle Main Engine. The results presented in this study could be an appropriate indicator for a good bond of EDNi/DECu/NARloy-Z layers with the desired thickness of copper deposition in the SSME MCC manufacturing process. Furthermore, the results from this study appear to be applicable to any bonded joints that can be characterized by the parameters and assumptions used in this analysis. Author (revised)

ELASTIC DEFORMATIONS AND SOUND IN ANISOTROPE SUPERCONDUCTORS NEAR CRITICAL TEMPERATURE [UPRUGIE DEFORMATSII I ZVUK V ANIZOTROPNYKH SVERKHPROVODNIKAKH VBLIZI KRITICHESKOJ TEMPERATURY]
Y. M. Poluehktov 1991 20 p In RUSSIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-620636; KFTI-91-17) Avail: CASI HC A03 (US Sales Only)

The influence of elastic deformations on the characteristics of anisotropic superconductors was investigated within the framework of elasticity theory and Ginsburg-Landau theory. Propagation and damping of sound in these superconductors near the critical temperature T(sub c) was considered. Sound velocity makes a jump and damping increases at T(sub c) point. It was shown that the magnetic field decreases in value and changes in direction when it penetrates an anisotropic superconductor. DOE

The software used to perform sinusoidal and random vibration analysis has been evaluated. The effects of changing the parameters in the test setups were studied. In doing this, the capabilities and limitations of the software have been noted and documented in the operating procedures for the systems. By documenting the software capabilities and limitations, the operation has been improved by avoiding operations that are not possible with the current software. The operation has also been improved through a better understanding of the effects of test parameter changes. The procedure for performing random vibration analysis has been updated. A procedure for performing sinusoidal vibration analysis has been issued. DOE

Specific forms for both the Gibb's and the complementary dissipation potentials were chosen such that a complete potential based multiaxial, isothermal, viscoplastic model was obtained. This model in general possesses three internal state variables (two scalars associated with dislocation density and one tensor associated with dislocation motion) both thermal and dynamic recovery mechanisms, and nonlinear kinematic hardening. This general model, although possessing associated flow and evolutionary laws, is shown to emulate three distinct classes of theories found in the literature, by modification of the driving threshold function F. A parametric study was performed on a specialized nondimensional multiaxial form containing only a single tensorial internal state variable (i.e., internal stress). The study was conducted with the idea of examining the impact of including a strain-induced recovery mechanism and the compliance operator, derived from the Gibb's potential, on the uniaxial and multiaxial response. One important finding was that inclusion of strain recovery provided the needed flexibility in modeling stress-strain and creep response of metals at low homologous temperatures, without adversely affecting the high temperature response. Furthermore, for nonproportional loading paths, the inclusion of the compliance operator had a significant influence on the multiaxial response, but had no influence on either uniaxial or proportional load histories. INTEGRAL EQUATION METHODS FOR MIXED BOUNDARY PROBLEM OF FRACTURE MECHANICS Ph.D. Thesis
Jianhua Li 1992 84 p
Avail: Univ. Microfilms Order No. DA9310044

A mathematical model to study a mixed boundary value problem of fracture mechanics, embedding the interface crack in a nonhomogeneous boundary layer, is developed. A general solution for a nonhomogeneous finite strip is found. The boundary value problem is reduced to a pair of 'dual integral equations'. Using the Hankel transform or the Fourier transform, the dual integral equations are reduced to a Fredholm integral equation of the second kind with a weakly singular kernel and a Cauchy integral equation (CSIE) of the first kind with a strong singular kernel, respectively. The Fredholm weakly singular integral equation (WSIE) is solved approximately by the product integral method. In order to develop a numerical method to solve CSIE with variable coefficients, the singular weight function technique is extended, as a complement to constant coefficient case. The discrete system of nonlinear equations to determine the exponents of the singular weight function is constructed through Gauss-Lobatta-Chebyshev method (GLCM) or Stengers formula. Using Newtons method, the nonlinear system is solved numerically. The convergence of the Newton iterative process is proved. Furthermore, employing the orthogonality property of the solution spaces of Cauchy type integral operator and its adjoint operator, a new direct numerical method for solving nonhomogeneous CSIE with variable coefficient is found and implemented. The numerical simulations of these methods gave excellent results for computing stress intensity factor and crack energy of the mixed boundary value problems and for a number of interesting examples. The numerical results are tabulated and shown graphically. Dissert. Abstr.

ACTIVE VIBRATION CONTROL OF ADAPTIVE FLEXIBLE STRUCTURES USING PIEZOELECTRIC SMART SENSORS AND ACTUATORS Ph.D. Thesis

Suk-Yoon Hong 1992 176 p

Avail: Univ. Microfilms Order No. DA9311652

The active control of vibrations and radiated noise from structures is studied. The emphasis of the theoretical and experimental study is the use of a minimum number of discrete piezoelectric wafer type sensors and actuators and optimal control algorithms. One of the major objectives is to effect control without substantially changing the structural dynamics of the original system. Canonical structures such as a cantilever beam and an all-clamped square plate, as well as practical structures such as fuel tanks, are investigated to cover a wide range of structural vibration control problems. For the suppression of a single mode as well as for multi-mode structural motions, velocity feedback and coupled model steady-state quadratic optimal control methods are applied using both analog and digital control systems with the various types of PZT (Lead-Zirconate-Titanate) transducers. The advantages of circular disc type PZT wafers are explained and a uni-disc type co-located sensor and actuator system was proposed. For more efficient filtering of the structural mode signal, a smart filtering idea was developed considering the mode shape and poling direction of the sensor. To convert the signals from a partially distributed sensor and actuator to a point displacement and forcing signal, respectively, efficient conversion methods are developed. From the experimental and theoretical studies on the optimum selection of actuator positions, a coupled mode optimal control simulations is executed. On the basis of all the related theories and the developed ideas and control systems, a variety of adaptive structural vibration control experiments are performed verifying the potential of PZT transducers as sensors and actuators. Both single mode and multimode control of structural vibration and radiated noise was achieved in all cases. Using at the most 1-4 small disc or ring-shaped actuators, the original vibration levels were reduced by 12-25 dB. Successful vibration control of the automobile fuel tank indicates that the ideas proposed and implemented can be applied to several practical structures such as the passenger compartments of ground and airborne vehicles. Such structures which adapt themselves to different types of sources and environments can be called 'Smart Structures'.

LABORATORY STUDIES ON THE VELOCITY OF FRAGMENTS FROM IMPACT DISRUPTIONS Report No. 651

Akiko M. Nakamura Jul. 1993 94 p

Avail: CASI HC A05/MF A01

The velocity distribution of fragments from impact disruption was experimentally determined as a step toward better understanding of the collisional evolution of planetary bodies. Ejection velocity and rotational frequency of fragments larger than approximately 1 mm were investigated by taking 16 mm pictures. Basalt, alumina, and gypsum spheres of 4 cm to approximately 8 cm in diameter were shattered by nylon spheres 7 mm in diameter at velocity of 1 km sec(exp -1) to approximately 4 km sec(exp -1). In order to investigate the velocity of fine fragments 1 micrometer to approximately 100 micrometers in size, new impact disruption experiments of basalt blocks were performed, where thin films and foils were exposed to the ejecta as a secondary target. The velocity of fragments was estimated by the size distribution of holes perforated on the secondary target. A comprehensive compilation of velocity data is proposed. The results are reported with emphasis on the relation to the dimension of the fragments. For large fragments of the three target materials, similar relations between the velocity in the center of mass system and the size are obtained. The velocity dispersion of a given fragment size is within about one order of magnitude. The slopes of log-log relations of the velocity versus the size range from -1 to -1/2. Although the size-velocity relation of smaller fragments depends on the ejection angle, the results suggest that the systematic relation of mm- to approximately cm-sized fragments can be extrapolated to smaller sized fragments. The rotational frequency decreases with increasing size of the fragment. It is shown that the laboratory data and data on the crate ring on the Moon can be conformed to a single dimensionless size-velocity relation, V(s) = V* (Y,rho,C) (s/a)(exp -xi) (1/2 less than or equal to xi less than or equal to 1), where V(s), V* (Y,rho,C), Y, rho, C, and a denote the representative velocity of fragments of size s, a function with dimension of velocity, strength of the target, target density, sound velocity of the target, and the size of the projectile, respectively.

An attempt to produce images of temperature fields simulated by the radiative transfer model (LOWTRAN-6) is performed. Two different types of images are produced. One is the water vapor image (Simulated Water Vapor, SWV image) based on temperatures calculated in the same wavelength as the water vapor channel (channel 12) of HIRS/2, and the other is the infrared split image (Simulated Split Pseudo color,SSP image) based on temperature difference (channel 4-5) calculated in the same wavelengths as the infrared split channels (channel 4 and 5) of Advanced Very High Resolution Radiometer (AVHRR) on NOAA-11. In the computation of the radiative transfer model, the following assumptions are made. Atmospheric vertical data (height, temperature, and humidity) provided by the numerical forecast division, JMA, are utilized. The lowest vertical level (1000 hPa) is assumed as the surface of the earth and its emissivity equal to unity. The filter functions of NOAA-11 HIRS channel 12, AVHRR channel 4 and 5 are assumed. Zenith angle is zero degrees. The following results are obtained by the comparison of the simulated images with the observed HIRS channel 12 (WV) image and AVHRR temperature difference (channel 4-5,SP) image. Warm regions relating to the dryness on the mid tropospheric layer are relatively well expressed on the SWV image. The boundary of temperature difference relating to the surface front and the regions with large temperature difference inferred to the moist regions of lower tropospheric layer are also relatively well expressed on the image. STATISTICAL STUDY ON THE REGIONAL AND SEASONAL DISTRIBUTION OF FOG IN THE FAR EAST REGION BY USING GMS IMAGERY **c47**
Motoi Matukawa *In its* Meteorological Satellite Center Mar. 1993 p 35-47 In JAPANESE (For primary document see N94-11079 01-42)
Avail: CASI HC A03/MF A01

Statistical investigation was made on the frequency of fog formations in the Far East region. The higher frequency regions are (1) the vicinity of Hokkaido and its eastern sea area, and (2) the southern part of China and the coastal area of middle China. In the region 1 it shows an annual variation (increasing in warm half year and decreasing in cold half year), but in region 2 peaks of the frequency appear in May, August, and December. (Contract DE-FG03-91ER-61198)
(DE93-011656; DOE/ER-61198/T2) Avail: CASI HC A09/MF A02

The Earth's climate has varied significantly in the past, yet climate records reveal that in the tropics, sea surface temperatures seem to have been remarkably stable, varying by less than a few degrees Celsius over geologic time. Today, the large warm pool of the western Pacific shows similar characteristics. Its surface temperature always exceeds 27 C, but never 31 C. Heightened interest in this observation has been stimulated by questions of global climate change and the exploration of stabilizing climate feedback processes. Efforts to understand the observed weak sensitivity of tropical sea surface temperatures to climate forcing has led to a number of competing ideas about the nature of this apparent thermostat. Although there remains disagreement on the processes that regulate tropical sea surface temperature, most agree that further progress in resolving these differences requires comprehensive field observations of three-dimensional water vapor concentrations, solar and infrared radiative fluxes, surface fluxes of heat and water vapor, and cloud microphysical properties. This document describes the Central Equatorial Pacific Experiment (CEPEX) plan to collect such observations over the central equatorial Pacific Ocean during March of 1993. DOE

A STATISTICAL METHOD TO DETERMINE AEROSOL PATH RADIANCE AND ITS APPLICATION TO ATMOSPHERIC CORRECTION FOR CZCS IMAGERY c46

Hua Qi, Kazuhiko Oonuma, and Yoshizumi Yasuda *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 15-20 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

An accurate method to eliminate the large signal component due to the atmospheric scattering is required to obtain quantitative ocean color measurement in remote sensing. The most widely used atmospheric correction for CZCS (Coastal Zone Color Scanner) sensor, proposed by Gordon et al. (1983, 1988), utilizes the 'clear water radiance concept' to determine the aerosol parameters which is the most important parameter. However, the 'clear water radiance concept' has been reported to be useless against a significant portion of Japanese CZCS data sets. This is considered to be due to a generally turbid atmosphere in the region. This paper is to examine a statistical method to obtain the aerosol parameter epsilon (lambda, 670) based on an idea that the aerosol scattering pattern has no correlation with the ocean color pattern. The method is applied to a sequence of CZCS imagery around Japan and the results are compared with the results given by the clear water method. The wavelength dependency of aerosol parameters is also discussed. Author (NASDA)

EFFECTS OF WIND-ROUGHENED SEA SURFACE ON OCEAN COLOR REMOTE SENSING: NOISE DERIVED FROM REFLECTED LIGHT AND WHITECAPS c48

Susumu Kanno *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 21-26 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Some problems in atmospheric correction of ocean color remote sensing which derived from reflection of incoming light by wind-roughened sea surface are discussed. Reflectance of ocean surface is calculated with the aid of wave slope distribution and effective reflectance of whitecaps. These effects are estimated as the error in retrievals of waterleaving radiance and phytoplankton pigment concentration. The error in retrieval increase with wind speed, solar position, and pigment concentration. Airborne remote sensing data is processed with the atmospheric correction algorithm including the effects of ruffled sea surface and compared with conventional one. The difference from the image of waterleaving radiance retrieved by conventional algorithm is clearly shown although little difference of phytoplankton pigment concentration appeared in each image. The proposed algorithm is particularly suited for the condition that wind speed, solar position, and pigment concentration are relatively high. Author (NASDA)

SATELLITE OBSERVATIONS OF RED TIDE EVENTS: PLANS FOR EESI c48

J. F. R. Gower *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 27-33 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

A recent occurrence of a major red tide event on the west coast of Canada demonstrated the value of satellite images for mapping their occurrence and extent, but also showed the need for an improved satellite sensor. The EESI (Earth Environment Space Initiative) satellite, designed in Canada as part of the national space program, meets many of the requirements for studying such events. It is being designed to give wide-swath visible imagery having a spatial resolution intermediate between the AVHRR (Advanced Very High Resolution Radiometer) and the TM (Thematic Mapper), with near-daily coverage. Spectral band positions and sensitivities would be more suitable for water observations than those of either the TM or AVHRR. Author (NASDA)

AN ALGORITHM FOR THE DETECTION OF MUCILAGE (GREEN SLIME) IN THE ADRIATIC SEA c48

Stelvio Tassan *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 34-39 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

In the summer of 1989, an exceptional production of mucilaginous matter occurred in the Adriatic Sea, forming slimy patches driven around by winds and currents. The presence of this 'mucilage' spoiled the tourist season. The phenomenon, which depends on a combination of favorable meteorological conditions, is not rare in the area. Its identification by remote sensing techniques, beside being clearly useful for the timely organization of appropriate safeguard measures, may also help to identify the still unknown cause of the phenomenon. The Advanced Very High Resolution Radiometers (AVHRR) on board NOAA-10 and 11 cover the same zone of the earth twice a day (in daylight), providing time series of considerable value. This paper summarizes the results obtained in setting up an algorithm for mucilage monitoring which uses AVHRR data. An algorithm for mucilage detection using AVHRR data and including a cloud-screening routine was developed and tested versus sea truth provided by a TM (Thematic Mapper) scene. The algorithm seems to meet the prescribed reliability requirement over a large variety of atmospheric conditions. Apart from providing for mucilage identification, the algorithm also yields information on the mucilage density. The small computational effort required for the data analysis makes the procedure suitable for operational use. Author (NASDA)

REMOTE SENSING OF THE SUSPENDED MATTER DISTRIBUTION WITH HIGH CONCENTRATION IN CHINA SEA c48

Jun Ma, Xiao-Sheng Huang, Mao-Chong Shi, and Zhi-Shen Liu *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 40-46 Sponsored by China National Foundation of Natural Science (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The pattern recognition method has been successfully applied to remote sensing the suspended matter distribution with high concentration. Using multispectral radiance, the characteristic signature of suspended matter with characteristic vectors, and concentration of suspended matter with eigenvalues were depicted. This paper describes a characteristic vector analysis of 38 sea surface water reflectance spectra acquired from a ship in the mouth of Yellow River, China. Four vectors are sufficient to account for over 4 percent of the variance in all cases. Linear combinations of the scalar multipliers can be used to estimate the suspended matter content. A good correlation (correlation coefficient = 0.91) is obtained between them. Thematic Mapper data were analyzed for mapping the suspended matter distribution. The first vector appears to be dominated by the backscatter effects and the atmosphere effect is removed. Author (NASDA)

An HF (High Frequency) ocean radar has been developed at Okinawa Radio Observatory. This radar is the first ocean radar aiming at to be used for a remote sensor for the oceanography in Japan. The radar is the groundwave, narrow beam radar. The radar is FMICW (Frequency Modulated Interrupted Continuous Wave) radar with peak power 100 W. After 1988, several performance test observations have been done and it is confirmed that this HF ocean radar has a potential to measure the ocean current about 80 km range, the wave height up to about 30 km range, and wind direction. Another HF ocean radar having almost the same performance as the first radar has been developed for the precise measurement of the ocean current vector. Author (NASDA)

Ocean currents observations in the Tokara strait were carried out at Yakushima and Tanegashima from October to December in 1990, using the HF (High Frequency) ocean radar which was developed by the Okinawa Radio Observatory of Communications Research Laboratory (CRL). It can measure the line-of-sight velocities of surface currents over the range of 50 km. Kuroshio are investigated from the time series of the current velocities over two months. The changes of the current velocities which might be caused by the moving of the location of Kuroshio are detected by the ocean radar. Author (NASDA)

STATISTICAL STUDY OF HF OCEAN RADAR ECHO c32

Akitsugu Nadai *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 65-70 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The difference of surface velocities extracted from two first order echoes backscattered by approaching and leaving wave is studied statistically. The result is that the difference is smaller than the resolving power of HF (High Frequency) ocean radar, but some data shows a large difference. The studying of Doppler spectrum shows that the splitting of first-order echo is the reason of this large difference. Simple calculation shows the probability that the broadening and splitting of first-order echo is produced by the distribution of surface velocity in radar target cells. Author (NASDA)

GROUNDWAVE HF OCEAN SURFACE RADAR c32

M. L. Heron and N. R. McLaren *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 71-75 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

This paper reviews the performance of the James Cook University Coastal Ocean Surface Radar (COSRAD) system. COSRAD is an HF (High Frequency) ocean surface radar and has the advantage of a narrow steerable beam for both the transmit and receive functions. The operator can focus all the radar energy onto one sector. The transportable 30 MHz COSRAD system has been used in many locations and this is discussed showing measured currents in a coastal area where water quality is a concern. A long range groundwave radar has been tested in Australia. This system can observe surface currents and wave data beyond 200 km from the shore-based radar site. Design trade-offs in this system require a longer integration time on each viewing direction in order to achieve a constant resolution of surface current as lower HF radar frequencies are used to obtain longer ranges. Both of the existing systems, at 30 MHz and 6.77

MHz operating frequencies, have relatively coarse spatial resolution of approximately 2 km and 15 km respectively. The need often arises for a current mapping radar with finer spatial resolution to around 100 m. The Marine Radar Group at James Cook University are developing a VHF radar operating in the 150-200 MHz range. This system has a spatial resolution down to 100 m and an operating range of a few kilometers for observing surface currents. The Bragg resonant sea waves for this system are 0.75-1.0 m and the echo spectra are heavily modulated by swell and wing waves. Author (NASDA)

This paper describes the processing procedures of NOAA-AVHRR (Advanced Very High Resolution Radiometer) data for the retrieval of SSTs (Sea Surface Temperatures), validation of the satellite derived SSTs, and their oceanographic and fishery applications. In order to study the activities of monsoons, the oceanic response has been realized in the recent past. The very long coast line of India stretching about 7,500 km in length provides a unique opportunity for exploring the use of remote sensing technology for identifying Potential Fishing Zones (PFZs). The use of NOAA-AVHRR data by way of retrieving SSTs on near real time basis for forecasting PFZs is made operational during the fishing seasons along east and west coasts of India. The SST information is also being used to study the Indian summer monsoon vagaries. Satellite based potential fishing zones have resulted in three to four fold increase in the fish catch during the lean periods. The Somali current with its associated upwelling and the formation of two gyre system along Somali coast during summer monsoon 1991 have been discussed in relation to the variations of summer monsoonal rains over India. The NOAA-AVHRR derived SST information is found to be useful in identification of potential fishing zones and to study the monsoon vagaries over India. Author (NASDA)

In the field of fisheries, NOAA/AVHRR (Advanced Very High Resolution Radiometer) imageries have become widely used for detecting fishing grounds through fishery-aid charts. However, more expert knowledge and experience are needed to complete a more detailed chart. A computer-processed fishery and oceanographic condition chart using satellite information have been studied. In this paper, the use of PCA (Principal Component Analysis) for IR (Infrared) data is discussed. First, calculate the SST (Sea Surface Temperature) gradients in four directions per pixel in AVHRR imagery. Then, obtain four values for all pixels in an area and carry out a PCA using these data. The maximum eigenvector of first principal component should signify the direction and value of major SST gradients in the area. Thus, the key vector can provide with a distribution of major water masses for some area data and their continuity or movement for time-series area data. Furthermore, the first principal component score chart for each pixel must enable us to estimate the oceanographic characteristics in the area. These features are considered to be useful for modeling oceanographic conditions from satellite imagery data using AI (Artificial Intelligence). Author (NASDA)

The RV (Research Vessel) Natsushima of Japan Marine Science and Technology Center (JAMSTEC) made two cruises in the equatorial Pacific in January-February 1989 and in January-February 1990 as part of the Japanese Pacific Climate Study (JAPACS) program. These cruises spanned the central and western Pacific along the equator to sample conditions in both the equatorial cold tongue east of the dateline and conditions in the warm pool west of the dateline. Cruise in 1989 was performed during predominant La Nina conditions in which the SOI (Southern Oscillation Index) showed largest positive anomaly since 1976, and cruise in 1990 during El Nino like conditions in which the SOI showed extremely negative. The surface wind, temperature, salinity, and current data set along the equator obtained in these cruises enabled us to depict uniquely the oceanic response in the context of El Nino and Southern Oscillation. ACOUSTIC WAVEGUIDE CHARACTERISTICS OF THE INDIAN OCEAN NORTH OF EQUATOR **c48**

S. Prasanna Kumar, T. V. Ramana Murty, Y. K. Somayajulu, and C. S. Murty *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 106-111 Sponsored by Dept. of Ocean Development (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The acoustic characteristics of the waters of the Arabian Sea and Bay of Bengal, constituting the northern Indian Ocean, are analyzed based on a climatological mean sound speed field. In the upper 30-40 m in the Bay of Bengal, a weak surface duct is noticed. The depth of the SOFAR (Sound Fixing and Ranging) axis varies from 1,400-1,950 m in the Arabian Sea and from 1,100-1,750 m in the Bay of Bengal. While the depth of the SOFAR axis increases towards the northern latitudes in the Arabian Sea, it decreases in the Bay of Bengal. The axial sound speed varies from 1,492-1,496 m/s in the Arabian Sea and from 1,492-1,494 m/s in the Bay of Bengal. A feature important and common to both Arabian Sea and Bay of Bengal is the depth limited nature of the sound speed profile. As a consequence the effective waveguide lies much below the sea surface (100-300 m). The acoustic ray arrival pattern, obtained from ray computations, reveals that rays with emergence angles between 6.5 and 7.5 deg in the Arabian Sea reach the receiver first followed by the flat angle rays and steep RBR (Refracted Bottom-Reflected) rays. In the Bay of Bengal, flat angle rays reach faster than the purely refracted steep angle rays. This arrival pattern is, due to the presence of a weak acoustic waveguide in the northern Indian Ocean, contrary to the arrival sequences reported for the Atlantic and the Pacific Oceans. ONE-YEAR MOORING OF AN ADCP IN THE CENTRAL REGION OF THE KUROSHIO WEST OF OKINAWA **c48**

Hideo Nakajima, Arata Kaneko, Noriaki Gouda, Kazuo Kawatate (Kyushu Univ., Fukuoka, Japan.), and Shinjirou Mizuno (Kyushu Univ., Fukuoka, Japan.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 112-115 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

A first long-term profiling measurement of the Kuroshio has been carried out by using a moored ADCP (Acoustic Doppler Current Profiler) in the central region of the Kuroshio west of Okinawa during the period of December 1989 to November 1990. A clear spectral peak related to the cross-streamwise movement of the Kuroshio axis was found to form at the period of 15 days. The monthly mean currents showed a remarkable slackening of magnitude in the surface layer especially in the period of August to November in 1990. On the basis of the EOF (Empirical Orthogonal Function) analysis, it is suggested that the slackening of the Kuroshio in the surface layer is replaced by the generation of wind-driven currents in this layer. A bottom-moored ADCP (Acoustic Doppler Current Profiler) was recovered successfully after continuous use during December 1990 to November 1991 in the Kuroshio on the East China Sea shelf slope. The raw ADCP data sampled every one hour with a depth bin of 8 m were smoothed through a filter of one month. The current flowing to the northeast along the isobathes showed vertical profiles of decreasing linearly from the surface to bottom. In August, the northeast current was confined to the upper 200 m of water and the weak reverse current formed in the deeper water. The near-bottom current perpendicular to the isobathes was directed to climb down the East China Sea shelf slope. Author (NASDA)

A Multipaths Inverted Echo Sounder (MIES) was developed and tested for measuring vertical average currents by accurately measuring time differences for sound wave to travel in two opposite directions along a path in the ocean. The acoustic path's 'sing around' vertical triangle, with a base of approximately 10 km long, and the time differences determine the horizontal component of velocity averaged through the water column. The field tests were conducted by using two MIES. Each MIES provides the function of transponder and records all data. The results of the field tests are presented and discussed. Author (NASDA)

A side scan sonar, a sub-bottom profiler system for the 10,000 m class ROV (Remotely Operated Vehicle), was developed to observe both surface and sedimentary layers of several thousand meters in depth. The side scan sonar has two transducers with the frequency of 38 and 42 kHz in each side of the ROV. Acoustic imaging of the sea bottom of 1 km width in each side was obtained with the use of 2 deg beam width transducer. Using a parametric array, a technology of the nonlinear acoustics in the sub-bottom profiler, we realized a very narrow beam width of 5 degrees with the frequency of 3.5 kHz. In this report, acoustic characteristics of this equipment are measured in a water tank and experimental results in shallow water are shown. Author (NASDA)

A high-speed and reliable video transmission system of color pictures from an underwater vehicle to a sea surface vessel by digital acoustic signal has been developed for real-time deep-sea viewing on the support vessel. The color video picture transmission by a digital acoustic signal has been studied, and it achieved good results in the transmission from 3,500 m depth in 1988. Then based on these studies, Japan Marine Science and Technology Center (JAMSTEC) has produced the practical system for the deep-sea submergible 'Shinkai 6500' and its support vessel 'Yokosuka' (6.5 K system). A sea trial of the system was carried out at the Ryukyu trench (about 6,500 m depth) in March 1992, and the clear video picture of the sea bottom on 'Yokosuka' was succeeded to receive at a rate of 8 seconds per a frame. The focus of this research is on utilizing all available data (remotely sensed and in-situ) to objectively produce ocean-atmosphere fluxes of momentum and latent and sensible heat to serve as forcing fields as well as guides for model products and by-products. A variational objective analysis technique is used to operate on all available in-situ as well as remotely sensed wind, temperature, and humidity data to calculate surface flux fields of wind stress and sensible and latent heat flux during the SEASAT mission. The technique forces interdependencies amongst the fluxes so that the resultant fields of winds, temperatures, humidity, and momentum as well as heat fluxes are consistent with the bulk formulations as well as with each other. Thus, the resulting maps not only include fluxes, but the component fields as well. This analysis has been completed for the north Atlantic region during the 5 day SEASAT mission. Results from the investigation of the temporal and spatial variability of the wind stress and heat flux fields are presented. Author (NASDA)

Spaceborne microwave radiometers have provided accurate observations of water vapor over the oceans. Water vapor is an important greenhouse gas. At periods longer than a week, the column-integrated water vapor is found to be closely related to surface level humidity which is needed to compute evaporation from the ocean. Evaporation and precipitation derived from satellite data were combined to approximate hydrologic forcing on the ocean. The forcing was found to agree with the climatological seasonal distribution of surface salinity. Sea surface temperature as a determining factor in evaporation change was examined but no significant positive contemporary correlation was found: higher sea surface temperature does not necessarily correspond to high evaporation. However, significant negative lag correlations were found: increase in evaporation lowers sea surface temperature a few months later in most of the ocean. There is a strong relation between greenhouse effect and the water vapor in the atmosphere over most of the tropical and mid-latitude oceans, but the relation is not as simple as previously prescribed. Exceptions were found in the equatorial regions where temporal correlations between water vapor and sea surface temperature are low, and in high latitudes where the annual cycles of greenhouse effect are out of phase with sea surface temperature. A new set of empirical formulas for the production rate and the number concentration of seawater droplets on the sea surface are proposed, synthesizing past observation data of sea-salt particles in the sea and water droplets in wind-wave tanks. A new level z(sub c) is introduced as the effective wind-sea surface where sea-water droplets are produced. The new formulas are expressed in linear functions in logarithmic scales of u(sub *)(exp 2)/nu sigma(sub p), a parameter to describe overall conditions of air-sea boundary processes, where u(sub *) is the friction velocity of air, nu the kinematic viscosity of air, and sigma(sub p) the peak angular frequency of wind-wave part of wave spectra. A model of coexistence of spray droplets and suspended particles near the sea surface is proposed. As for the independent parameter, a comparison between the uses of u(sub *)(exp 2)/nu sigma(sub p) and u(sub *)(exp 3), which was the traditional way of parameterization excluding wave measure, shows that the advantage of using u(sub *)(exp 2)/nu sigma(sub p) is statistically significant with a confidence limit of 89% in F-test. A feature of latent heat flux data in TOGA (Tropical Ocean Global Atmosphere) CD-ROM which was given by the ECMWF (European Center for Medium Range Weather Forecasts) has been investigated for different time scales with emphasis on the tropical ocean. For a monthly-mean time scale, the magnitude is smaller than climatology in the Pacific Ocean, probably because wind fields of the ECMWF model is weaker than the nature. For a synoptic time scale, it can qualitatively represent the fluctuations associated with tropical disturbances of 2,000 km scale. It is concluded that latent heat flux estimated by numerical models can be used in a qualitative sense for studying a behavior of disturbances over the tropical ocean. Author (NASDA)

For a statistically stationary wave field, analysis of wind-to-wave energy and momentum exchanges is carried out by employing integrated equations of wave action, energy, and momentum transfer. Equilibrium range of wave spectra is presented by a power law in which the effective exponent and the Phillips constant depend on the wave age. Two regimes of wind-wave interactions are identified: the regime in which the direct energy cascade through the wave spectrum is a dominant factor of wave dynamics and that in which the inverse cascade dominates. For the latter case, the present understanding of wave dynamics appears to be insufficient. Finally, the drag coefficient is inferred from the momentum balance equation and shown to exhibit the wave-age dependence observed in field experiments. Energy and momentum transfer coefficients from wind to waves are estimated indirectly by comparing theoretical behavior with field observations. One of the conclusions is that the main sink of energy and momentum may be associated with larger-scale motions excited by the wave field, rather than with small scale breaking waves. Author (NASDA)

The direct measurement of the sea surface heat flux was started in October 1990 using automatic weather-station system. The measuring system is set on a ferryboat between Okinawa and Taiwan (the beginning region of the Kuroshio). Using the measured data (one year) and additional data from the logbook of the ferryboat in recent five years (1986-1990), the seasonal and spatial (mesoscale) variability of the surface heat flux in this region is discussed. The GMS (Geostationary Meteorological Satellite)-visible image data is also used in conjunction with the field data to estimate the spatial distribution of the solar radiation. Author (NASDA)

Seasonal variation of the heat balance in the surface mixed layer in the vicinity of the former OWS-T (Ocean Weather Station 'Tango') south of Japan where a large amount of heat transported by the Kuroshio is distributed by three dimensional processes in the sea and transferred to the atmosphere was studied during OMLET (Ocean Mixed Layer Experiment) which is an oceanographic component of the Japanese WCRP (World Climate Research Program). Four time series, total 669 days, of temperature and currents data in the upper ocean were collected from a surface moored buoy system for the periods of April 18, 1988 to November 2, 1988 (OMLET88), August 12, 1989 to February 26, 1990 (OMLET89), April 18, 1990 to September 8, 1990 (OMLET901), and September 9, 1990 to January 15, 1991 (OMLET902). In this paper, the moored data of upper 100 m for the later three time series (OMLET89, 901, 902) were analyzed and the heat balances were discussed. A large fluctuation of oceanic convergence/divergence, 200-300 Watt/sq m in amplitude and predominant periodicity of 20-30 days, occurred in the early half period of OMLET89 when it was early in the formation process of a large meander path of the Kuroshio. A large amount of heat convergence of 60, 71, and 15 Watt/sq m in the average over each period was estimated, respectively. It was found that those variations of oceanic heat convergence in this region were closely related to the behavior of the Kuroshio axis south of Japan.

Using a three dimensional heat flux model, variation of heat storage in the mixed layer of a triangular oceanic area, embedded in the Kuroshio has been studied for a period of a few days in the month of November, 1983. For the estimation of vertical heat flux across the air-sea boundary, both satellite (NIMBUS-7 SMMR (Scanning Multichannel Microwave Radiometer)) and ship observations are used. The advective fluxes across the lateral boundaries of the system are derived from sequential images of AVHRR (Advanced Very High Resolution Radiometer). The net heat divergence of the triangular system is obtained as the residual of these computed estimates of vertical and advective fluxes. The net heat loss of the system from heterogeneous data sets (ship and satellite) is found to be 4.8 times 10(exp 13) W. Whereas, using only ship observations, the net heat loss is found to be 2.3 times 10(exp 13) W. It is presumed that this observed difference in the two separate budgets is imparted through the better spatial resolution of SMMR derived wind speed and precipitable water.

Two methods to estimate solar radiation over oceans near Japan with Japanese Geostationary Meteorological Satellite (GMS) are presented. One is the estimate by means of cloud amount derived from cloud imagery by GMS. An empirical formula that connects the solar radiation at the sea surface with cloud amount estimated by the satellite is proposed. The other is the estimate based on histogram data of T(sub BB) (Blackbody Temperature) at cloud top. It was found that reduction rate due to high-level clouds is greater than that due to low-level clouds, suggesting that information of cloud height is needed in addition to total cloud amount to make better estimates of solar radiation at the surface. Vietnam has more than 3,200 km of shoreline, the problems of coastal and marine management are of major concern. The objectives of this study is to develop technology procedure of application of remote sensing and GIS (Global Information System) to shoreline change detection and to shoreline change map for entire Vietnam coastline as well as for most important estuaries in Red and Mekong river plains for period from 1930 to present. The multidate Vietnam shoreline maps on scale 1/250,000 produced from remote sensing data such as LANDSAT, SPOT, and Soyuz combined with other data sources and national topographic maps established in 1930 and other time at scale 1/100,000 were digitized and brought in to GIS, which is developed by Remote Sensing Application Division, for PC (Personal Computer) based system. The shoreline change analysis for period 1930-1965, 1965-1986 was carried out with some quantitative estimations by GIS-multilayer overlay technique. Based on obtained analysis results, all Vietnam shoreline has been classified as the following: accretion, erosion, mixed and permanent. The obtained results are not only used for a scientific purpose but are also used as data base components for coastal management in Vietnam. They show that shoreline problems could be successfully solved by using remote sensing and GIS. Author (NASDA)

An overview of the offshore application of satellite data (for such purposes as monitoring and protecting marine environment), the development of marine science training to produce highly-skilled specialists, access to satellite data, necessity of in-situ measurement by ships and buoys to enhance the effectiveness of the remote sensing, and remote sensing educational programs in the developing countries is presented. The conclusions are as follows: (1) oceanographers familiar with remote sensing should communicate their progress to others; (2) up-to-date, in-country

teaching and training applicable to the region should be implemented; (3) training should not be limited to professional maritime scientists but should also aim to make the administrators and program managers be aware of potential benefits of remote sensing; (4) space agencies should cooperate with science agencies to create a proper structure to widen the 'user community' of satellite data; and (5) a small fraction of financial commitment for current space missions should be dedicated to studying the ocean.

ANALYSIS OF THE CHARACTERISTIC AND MECHANISM OF SUSPENDED MATTER TRANSPORTATION IN HUANGHE DELTA SEA AREA USING REMOTE SENSING TECHNIQUES **c48**

Maochong Shi, Wei Huang, Ge Chen, and Mingxia He *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 205-210 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

In this paper, the distribution and transportation of surface suspended matter in the area from Bohai Bay to Laizhou Bay are analyzed using satellite data and in-situ currents data. It is concluded that in the summer the distribution of surface suspended matter has a close relationship with the residual currents in this sea area. In windless weather, the suspended matter brought by the runoff of the Huanghe River doesn't move toward northeast directly by the inertia but diffuses along the seashore. The nearby Wuhaozhuang is the only way for suspended matter to be transported to the outer sea. In the north of Dongfeng Port of Shandong Province, special eddies make clear water extend to the coast so that there is a fine condition for port-building. Author (NASDA)

In bathymetric study, if there are many bottom features in the study areas, it is necessary to analyze the information of the bottom characteristics in order to get accurate measurement on water depth. In the present study, the bottom features effect in Kin Bay, Okinawa Main Island, Japan, are analyzed using LANDSAT-5/TM (Thematic Mapper) and SPOT-1/HRV (High Resolution Visible Instrument) data. A bathymetry model was developed considering four types of the bottom features, namely, coral, sand, sand with a little of mud, and mud with a little of sand. According to the proposed model in this paper, the correlation coefficients of each bottom features between depth and digital counts are 0.40, 0.90, 0.57, 0.54 and 0.42, 0.95, 0.75, 0.07 for LANDSAT-5/TM and SPOT-1/HRV data, respectively. ON THE DETERMINATION OF THE SAR OCEAN SURFACE SCATTERING PATCH SIZE

I. Amadou and M. L. Heron *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 223-228 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

This paper discusses the imaging of ocean features by SAR (Synthetic Aperture Radar) through a variety of mechanisms. Fundamental to the derivation of the complex SAR images from the ocean is the identification of scattering points on the surface. The size of the scattering patch depends on the interactions of radar waves and ocean dynamics. The received signal from each point on a frozen (terrestrial) target is determined by the Doppler frequency shift corresponding to the approach velocity of that point. For a complicated moving target (oceanic) the point aperture becomes spread by additional velocity components within the target plane. The amplitude aperture thus formed, produces a self-interfering bundle of rays towards the receiver. Model calculations show that at low altitudes (air-borne) the image observed by the SAR receiver has a linear (or refraction) relationship with the ocean surface. However, at high altitude (satellite) and rough seas the image is nonlinear. It is shown that the scattering patch size is dependent upon look-angle, wave amplitude, platform altitude and velocity. THE OPTICAL/COMPUTER HYBRID PROCESSING OF EXTRACTING OCEAN WAVE DIRECTIONAL SPECTRUM BY AIRBORNE PHOTOGRAPH **c43**

Ming Xia He, Chao Fang Zhao, Xiao Dong Zhang, and Hui Fang *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 229-236 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

An optics/computer hybrid processing method to extract the ocean wave directional spectrum from a diffusion photograph is presented in detail. A thorough discussion of a remote sensing model, proposed by Stilwell, used to obtain the ocean wave directional spectrum is presented. The ocean wave directional spectra acquired by this method agree well with theory and in-situ data and are superior to those put forth in previous literature. The application research has been carried out in various sea areas of China. This method can be used as a validation of satellite SAR (Synthetic Aperture Radar)/ocean wave direction and can also be applied to theoretical studies of ocean waves, verification of an ocean wave forecasting model, and ocean engineering. Ocean-ice interaction processes in the Marginal Ice Zone (MIZ) by waves and mesoscale features, such as upwelling and eddies, are studied using Synthetic Aperture Radar (SAR) imagery and wave-ice interaction models. Satellite observations of mesoscale features can play a crucial role in ocean-ice interaction study. Author (NASDA)

The Lagrangian water motion and the resultant water exchange processes driven by variations in the Kuroshio, south of Japan, are studied by numerically tracking numerous labeled particles with the Euler-Lagrangian method. Temporal evolution of the fluid particle motion clearly shows that remarkable cross-stream exchange takes place in association with the formation and eastward progression of the Kuroshio meander: in particular, when the Kuroshio grows into a large-meander path, the cross-stream exchange is most striking. A close examination of temporal change in the vorticity balance along the stream reveals the generation mechanism. A growing meander mainly controlled by vorticity advection from the no-slip coast of Japan produces the regions with a negative minimum (positive maximum) value of temporal change in vorticity on the offshore (coastal) side of the Kuroshio axis near the apex of the meander. This drives local anticyclonic-motion (cyclonic-motion) of fluid particles across the stream, and eventually causes intense cross-stream exchange. The resultant particle distribution shows a fairly good similarity to thermal infrared pictures. These facts indicate that the cross-stream exchange driven by the Kuroshio path variation is one of the major factors that control the mass and heat transport processes in the ocean south of Japan. Formation process, frequency, and horizontal and vertical structures of giant warm streamers associated with warm-core rings in the Kuroshio-Oyashio transitional region are described. The study is based on the field observation made by using satellite thermal images of the sea surface, hydrographic observations with a CTD (Conductivity, Temperature, and Depth) meter and a ADCP (Acoustic Doppler Current Profiler), and a time series of current and water temperature with mooring systems and ferry boats. It was recognized that Warm Streamers (WSs) often branch out toward the north or northwest from Warm Core Rings (WCRs), in satellite thermal imageries. They become migration paths toward the north and from offshore to nearshore. In this study, the relationship between these fine structures and fishing grounds, are investigated, using NOAA AVHRR (Advanced Very High Resolution Radiometer) data with assistance of aircraft data and fisheries information. Obtained results are as follows: (1) NOAA AVHRR imageries with spatial resolution of 1.1 km well represent the structures of the WSs of about 10 km in width around the WCRs; (2) by using the simultaneous aircraft data, many sardine's schools are recognized at the head of WS, in which coastal region sardine's fishing grounds are often formed; (3) it seems that WS is useful for the transfer of schools toward the coast; and (4) schools of sardine, mackerel, and other species make zonation across the front of WCRs. The swift current with a sudden increase in temperature has been often observed in a coastal region, south of Japan, exposed to the north Pacific Ocean. Such phenomena are called the Kyucho in Japan. The Kyucho event also frequently occurs in Sukumo Bay, southwest of Shikoku. The causes of occurrence of the Kyucho event in the bay, however, have not been clarified yet. Seasonal variability of the Kyucho event in the bay are investigated to analyze surface temperature data obtained in and out of the bay from March 1990 to February 1991. The Kyucho event periodically occurs in the bay during the warming and cooling periods. Its average reoccurrence period is approximately ten and eight days during the two observation periods, respectively. Thermal infrared images obtained by the NOAA-11 in the sea off to the east of Kyushu are also analyzed. It is found that a warm filament derived from the Kuroshio is advected northeast to Cape Ashizuri-misaki along the Kuroshio, then it collides against the southwest coast of Shikoku, inducing the Kyucho event by the warm water intrusion in the bay. Based on a daily monitoring by the NOAA/AVHRR (Advanced Very High Resolution Radiometer), the coherent structure of extremely deterministic substances inside the oceanic turbulence fields around the Japan Islands Chain has been detected and researched. The satellite remote sensing and also the coherent structure concept are applied as the flow visualization technique and as the analyzing tool of turbulence. For the sea truth of the satellite survey, a series of hydrodynamical experiments are run in the rotating system. The site has some characteristics noticeable in the air, in the sea, and in the solid earth. In the atmosphere, extratropical lows sequentially pass through and typhoons approach sometimes. In the ocean, the Kuroshio mixes with the Arctic water and produces high energy of turbulence. The most characteristic nature of the solid earth is the periodic geometry of the sea basin. The cusped capes and arched bays succeed with a regular interval of about 100 miles. In this paper, it is discussed that the mechanical interactions among these elements in the air, in the sea, and in the solid earth reinforces the deterministic substances of the coherent structure remarkably. It is shown that the frequent passes of the atmospheric lows feed the turbulent energy and the cusped capes give tight locks on the eddy structure, and that the mechanisms result from the chaotic substances of the turbulence in the rotating system. Satellite radar altimeter data of GEOSAT during the first year of the Exact Repeat Mission are analyzed to estimate anomalies of the Sea Surface Dynamic Topography (SSDT) for the western north Pacific. They are compared with anomalies of the Sea Surface Temperature (SST) derived from NOAA Advanced Very High Resolution Radiometer (AVHRR). At mid-latitude, SSDT anomalies clearly show persistent westward propagation of both cyclonic and anticyclonic eddies. SST anomalies also reveal westward propagation, and this fact shows that these features are baroclinic. The propagation speeds of these features are roughly equal to those of the first mode baroclinic long Rossby waves, but the observed phase speeds differ from the phase speeds of Rossby waves, considerably at some latitudes. In the western part (140 deg E to 160 deg E), the observed westward speeds are slightly faster than the speeds of Rossby waves at all latitudes except for around 20 deg N, while in the eastern part (160 deg E to 180 deg E), they are slower at around 20 deg N and 28 deg N, and much faster at around 30 deg N. In the Kuroshio Extension region, SSDT anomalies show relatively constant propagation in the downstream region, while their propagations are complex in the upstream region.

COASTAL PROCESSES DUE TO NEARSHORE CURRENT AROUND AN UPHEAVING ISLAND **c48**

Masahiro Hashima and Yasuhiro Sugimori (Tokai Univ., Shizuoka, Japan.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 279-286 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

This paper concerns with the coastal processes of upheaving island due to near-shore currents. It is a well known phenomena that cusps form at the behind of a small island. If the island uplifts, coastal sands are transported by the littoral currents and cusps or sand spits are formed at the beach of the island. These phenomena have been observed remarkably at the upheaving island of Iwo-jima. In order to prove the mechanism that such cusps are formed, the longshore circulation due to waves breaking are calculated by numerical simulation. These currents are confirmed by experiments using a model and assumed by using air photographs. Then coastal processes of Iwo-jima are discussed. Author (NASDA)

The spiral precipitation bands that encircle mesoscale vortices and the thermal structure of the center domain are studied by satellite remote sensing data and radar. From the structure and environmental atmosphere of the vortices, it is confirmed that vortices form where three spiral precipitation bands around a vortex are successively intensified counter-clockwise. This occurs with increasing cyclonic curvature and moist convection in the convergence zone induced by cold air outbreaks.

The flow structure around a cylindrical pier is studied for the flow where Reynolds number is over 10(exp 8). The field measurement around Akashi Kaikyo Ohashi bridge pier was performed. The occurrence period of the shed vortex of the pier was about 30 seconds. In the rear side of the pier, large Karman vortices which had four times the occurrence period as that of the shed vortex could be seen. From the period of Karman Vortices, the Strouhal number in the region of transcritical Reynolds number is found to be 0.21. The flow was also simulated numerically by the three-dimensional flow analysis program, 'Flow 3D'. The result of the numerical simulation agreed well with the measurement. Author (NASDA)

In order to predict parcel paths for cold eddies as well as warm eddies, an f-plane reduced gravity model with upper-layer thickness and velocity fields was developed. This model reduced to eight dimensional system of nonlinear coupled ordinary differential equations, which describe time-evolution of kinematic differential parameters and eddy shape parameters. Although this eight-dimensional system of nonlinear coupled time-evolution equations can be solved numerically, exact solutions for a steady rotating mode of both warm and cold eddies were found. For warm eddies, the rigidly rotating ellipse mode solution is a generalization of the 'rodon' solution for lens-like warm eddies. The corresponding rigidly rotating mode solution for cold eddies shows triangular path with abrupt change of direction. Elliptical paths for warm eddies and triangular paths for cold eddies were observed in the drifter tracking data of the Western Pacific Ocean Circulation Experiment (WEPOCS) 3. It may be interpreted to be a manifestation of the rotating mode solutions predicted in this study.

NIMBUS-7 CZCS (Coastal Zone Color Scanner) DSP Level 2 images from NASA/GSFC (Goddard Space Flight Center) are used to form quarterly global chlorophyll fields over the western equatorial region (15 deg N to 15 deg S, 140 deg E to 170 deg W) for 1981 and 1982. Ocean color analysis combined with in-situ chlorophyll data from ORSTOM (Office de la Recherche Scientifique et Technique Outre-Mer) cruises (1988-1991) is successful in retrieving the variability of the phytoplankton enrichment due to the equatorial upwelling. The feasibility of a production estimation is analyzed from ORSTOM in-situ data. Author (NASDA)

Seasonal changes of phytoplankton distributions in the Pacific Ocean was described by simple statistics of 7-8 year monthly averages of Coastal Zone Color Scanner (CZCS) data. September data was also compared with ship-observed vertical chlorophyll distributions along 175 deg E. These data showed regional differences of the seasonal changes of phytoplankton concentrations. Subarctic front and coastline are the two major factors in determining the seasonal changes of surface phytoplankton pigment concentrations. Author (NASDA)

Four regions are identified in the western subarctic Pacific in the seasonal variability of the pigments field obtained by CZCS (Coastal Zone Color Scanner). Spring blooms appear in the offshore of northern Japan in April and shift to northeastward in May and June. In the Oyashio region, southeast of the Kuril Islands, pigment concentration is high in June, and September through November. High pigment concentration appears in the western subarctic gyre from October to December. Pigment concentration in the Kuroshio extension region shows moderate annual maxima in spring and fall. HIGH-REFLECTANCE WATER MASS IN OFF-SANRIKU AREA OBSERVED BY CZCS **c43**

Hajime Fukushima *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 336-340 (For primary document see N94-11894 01-42)
(Grant MOE-03248216)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Patches of high reflectance water are often observed in CZCS (Coastal Zone Color Scanner) data covering Off-Sanriku area, a northeastern part of marginal seas of Japan. The study is to investigate the spatial and temporal extent of the high reflectance waters as well as to validate the hypothesis that the phenomena is due to coccolithophore bloom. Eighty-nine of the total 301 CZCS scenes which covers the study area (35 deg N to 43 deg N, 140 deg E to 151 deg E) were selected in terms of low cloud coverage, with most of them obtained in 1979-1981. Atmospheric correction was done to all the selected scenes, applying a simple spatial filtering on the channel 4 image to avoid the effects of non-zero water-leaving radiance at 670 nm. The magnitude of resulting spectral reflectance was found to be at the same level as reported for coccolithophore blooms elsewhere in the world, suggesting the high reflectance patches were caused by detached coccoliths. The 'blooms' are popularly seen in May-August imageries with the length scale of several tens to 100 km. Author (NASDA)

PHYSICAL PROCESSES OF MICROWAVE BACKSCATTERING FROM LABORATORY WIND-WAVE SURFACES **c43**

Naoto Ebuchi, Hiroshi Kawamura, and Yoshiaki Toba *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 341-346 (For primary document see N94-11894 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Physical processes of microwave backscattering from laboratory wind-wave surfaces are investigated using an x-band (9.6 GHz) scatterometer. Time series of the displacement of water surface, the backscattered intensity, and the Doppler spectrum are observed and analyzed to study the relationship between the microwave backscattering and fine structures of the wind-wave surfaces. At large incident angles, the backscattered intensity is in phase with wave profile. Variation of the Doppler spectra also corresponds to the phase of the individual waves. High Doppler velocity observed at the crests of the individual waves coincides with the propagating speed of the crests. It is concluded that the fine structures of wind-wave surfaces, which are trapped near the crests and are propagating with the crests, mainly contribute to microwave backscattering. At the normal incidence, variation of the scattered intensity with the phase of the dominant waves is consistent with the specular point scattering. Author (NASDA)

This paper describes the experimental results of two campaigns carried out on board of the Italian National Research Council (CNR (Consiglio Nazionale delle Ricerche)) oceanographic platform in the northern Adriatic Sea. The aim of these as well as of the future campaigns is to measure the geophysical parameters influencing the radar backscattering from the sea surface, i.e. the wind speed and the sea surface elevation, and the radar backscatter itself. The radars used are three band (L, S, C) and single band (C) scatterometers. The sea surface elevation was measured, up to 26 Hz, by a microwave interferometric probe and the wind speed by a K-Gill two propeller anemometer. Results show the potentialities of the combined use of these instruments in studying the radar cross section sigma(sub 0) modulation due to the gravity waves and the low period (approximately 40 s) wind fluctuations, and the damping of sigma(sub 0) due to the presence of surface slicks. The examples reported here correspond to light wind conditions around 4 to 6 m/s. Author (NASDA)

MEASUREMENTS OF OCEAN CROSS-SECTION WITH A SIDE-LOOKING AIRBORNE RADAR c43

Hiroaki Horie and Kenji Nakamura *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 353-356 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

A result of measurements of ocean cross-section using an airborne real aperture side-looking radar is described. The radar cross section measurement is one of the objectives of the radar. In an observation of rain over ocean, an interesting phenomenon that the sea surface echo fluctuates with a shorter time scale in rain is found. It seems to be the interference of the rain echo and sea surface echo. Author (NASDA)

Air-sea interaction (ASI) should propably be a category, like oceanography and atmospheric science. At least for the purpose of funding. Too often, the problems and solutions for the interface between these two fluids is neglected. Perhaps it is always assumed by those in charge of one domain that it will be taken care of by the other. Another reason for the neglect of air-sea interaction is that not much is known about it. Measurements and theory are extremely difficult. The generation of waves inhibits both. The theoretical problem of wave generation has occupied some of the best fluid dynamics minds, and it cannot be said to be solved yet. A short review is made of research methods for air-sea interaction, their problems, and current status. Author (NASDA)

SCATTEROMETER OBSERVATIONS: REVIEW c43

Robert A. Brown *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 363-368 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The application of a new class of data such as that furnished by a satellite scatterometer requires a basic understanding of the nature of the data. The assumptions and techniques required to translate backscatter cross-section into surface stress, air-sea fluxes, wind profiles, and pressure fields are mentioned here. Although these involve a mixture of theory and parameterization, the results are convincing and rewarding. Author (NASDA)

Ocean observations taken by the satellite microwave radiometer SSM/I (Special Sensor Microwave Imager) show a variation that is correlated with the direction of the wind relative to the observation direction. For moderate wind speeds, the vertically polarized upwind brightness temperature T(sub B) is about 2 K higher than the downwind T(sub B). For horizontally polarized observations, the T(sub B) maximum occurs at crosswind rather than upwind and is approximately 3.5 K higher than the minimum at downwind. This SSM/I wind direction signal is used to make global, low-resolution maps of the monthly mean oceanic wind vector. These results indicate that it may be feasible to measure wind direction from space using a two-look microwave radiometer. Author (NASDA)

SURFACE ROUGHNESS VARIATIONS ACROSS THE ICELAND-FAROES FRONTAL REGION OBSERVED BY THE GEOSAT ALTIMETER AND NOAA AVHRR c43

Kaoru Ichikawa, John P. Matthews (University Coll. of North Wales, Bangor.), and Stephen B. Groom (Natural Environmental Research Council, Swindon, England.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 375-380 (For primary document see N94-11894 01-42)

Surface roughness variations across the Iceland-Faroes frontal region have been studied using NOAA AVHRR (Advanced Very High Resolution Radiometer) imagery and GEOSAT altimeter microwave echo intensity, sigma(sub 0). From the atmospheric boundary layer stability theory, substantial decrease of surface roughness is naively expected on the cold side. The frontal area was covered by an atmospheric high pressure system during May 21-25, 1987 and hence, the calm weather condition was satisfied. A synoptic view of surface roughness variation derived from the sunglint intensity variation in the visible bands of NOAA-9 AVHRR imagery within the calm weather period confirms the existence of the anticipated substantial roughness variation across the front. The profile of sigma(sub 0) along the GEOSAT track observed closest in time to the imagery also indicate flat surface on the cold water. In general, however, sigma(sub 0) profiles along GEOSAT tracks do not exhibit clear signatures at the front. One considered reason for this is that weather conditions to produce roughness changes observable by altimeter were severe in this region. It is also suggested from the image of sunglint variations that the intermittent presence of regions of anomalously flat surfaces play a role in masking the expected behavior at the front. Microwave backscattering from wind wave surface has been measured simultaneously with winds and waves in a large wind-wave tank by using a x-band scatterometer at .6 GHz with horizontal polarization. Various relations among the backscattered microwave power, incidence angle theta, characteristic wind speeds, u(sub *) and U(sub 10), and wind wave spectrum have been studied within the ranges -35 deg less than or equal to theta less than or equal to 35 deg and 3.5 m/s less than or equal to U(sub 10) less than or equal to 20.5 m/s, where u(sub *) is the friction velocity of the wind and U(sub 10) is the wind speed at the height z = 10 m, which is obtained by extrapolating logarithmic profiles of the wind. It is shown that the friction velocity depends on various quantities such as the wind speed U(sub 10), the backscattered microwave power, and the high frequency wave spectrum changes near the wind speed u(sub *) = 0.2 m/s and that these changing patterns are quite similar. The results show a close connection among the high frequency wave spectrum, the wind structure, and the backscattered microwave power. Author (NASDA)

Wind speed field in the north western Pacific is observed by using the GEOSAT altimeter and the SSM/I (Special Sensor Microwave Imager) of DMSP (Defense Meteorological Satellite Program) during the summer 1987 to 1988. Both sets of data are examined by the ocean data buoys near Japan and are validated. Characteristics of the wind velocity field in this area are investigated in detail and presented. Author (NASDA)

The wind speeds and significant wave heights derived from the GEOSAT altimeter are validated by comparing with the data obtained at Japanese ocean data buoy stations. A systematic error is found in the altimeter wind speeds at high winds. An experimental equation is derived in order to correct this error. By using the corrected wind speeds and the wave heights, growth of wind waves with fetch in the Sea of Japan under winter monsoon is investigated. The altimeter derived non-dimensional significant wave height and non-dimensional fetch show good agreement with the empirical fetch graph formulas. Author (NASDA)

Wind(-stress) fields on the sea surface over the north Pacific are derived from winds measured on ships-of-opportunity supplied by the Japan Meteorological Agency (JMA). Since the density of the ships-of-opportunity data is inhomogeneous in space, pseudo-stress data in the FSU (Florida State University) data set are supplemented in the poor-data area. Using time series of the zonal and meridional components in this data set covering a period of 27 years of 1961-1987, interannual variabilities are investigated. On time scales of several years, two dominant signals are found. These have periods of three to four years and about two years. The spatial coherences of the two signals are much different from each other. On a decadal time scale, gradual increasings of the stress magnitudes are found in the westerly and trade wind areas. The wind field based on ships-of-opportunity data is compared with that derived from satellite data (SSM/I (Special Sensor Microwave Imager)). The SSM/I winds are about 20 percent smaller in the mid-latitude area than the ship winds. Causes for these discrepancies are discussed. Author (NASDA)

Preliminary results of the study on obtaining wind data by using one hour Geostationary Meteorological Satellite (GMS) data are presented. The study was conducted to supplement the limited spacial scale of the Integrated Sounding System (ISS), which will be implemented around the Intensive Flux Area (IFA) for the Tropical Ocean and Global Atmosphere (TOGA) Coupled Ocean Atmosphere Response Experiment (COARE) to investigate an air-sea interaction for various temporal and horizontal scales. Comparable number of wind data were obtained by using one hour and 30 minutes GMS data, and the quality of the data from both GMS data seemed to be similar. These results support a possibility to obtain wind fields by using one hour GMS images. Author (NASDA)

While ocean circulation is mainly forced by surface wind stress, in-situ observations of ocean surface wind stress have been sparse. In the studies of ocean circulation through numerical models, climatological wind fields derived from ship reports and wind fields produced by operational weather forecast models have been used. Recently, a new wind data set was produced by R. Atlas by combining the wind speed measured by a spaceborne microwave radiometer and wind direction from in-situ measurements and models through a variational method. These wind fields were compared as forcings on the ocean. The responses of the ocean to these forcings were studied through the Ocean General Circulation Model (OGCM) developed at the Geophysical Fluid Dynamic Laboratory. The model was first forced by wind stress climatology. After a spin-up period, various wind fields were applied and the outputs of the model were compared with outputs from a controlled run using climatological forcing. As expected the OGCM shows temporal variations and reproduces El Nino anomalies when forced by ECMWF (European Center for Medium Range Forecasts) and SSM/I (Special Sensor Microwave Imager) winds which are absent from the response to climatological wind forcing. The SSM/I winds were found to cause more rapid cooling at the end of El Nino episode than the ECMWF winds. Author (NASDA)

A multi-parametric shipboard ocean lidar was developed and has been used to observe a vertical cross section of phytoplanktons and suspended solids in the upper layer of the water. This ocean lidar measures three parameters simultaneously, which include returns from the water surface, lights scattered by suspended solids, and fluorescent lights from phytoplankton. The returns from the surface were applied to evaluate the effects of the water surface for signals from the water. Through an experiment from the equator to the mid-latitude, this shipboard ocean lidar was operated to observe fluorescence and lights scattered with conventional measurements. The results showed the validity of this system to detect the change of phytoplanktons as a function of concentration of chlorophyll-a. Author (NASDA)

Underwater photogrammetry using a low cost camera system is capable of measuring the fine details of seafloor for sedimentation analysis. The system can be calibrated and the stereo models can incorporate the camera distortions. The resolution of the image in underwater situations is important

for photogrammetric measurement. One major factor which affects the image quality of an underwater object, as opposed to one in the atmosphere, is the water turbidity. In this paper, several experimental results of underwater stereo photogrammetry obtained in four different locations around Australia are presented. A technique to measure water turbidity was developed. Simple relationships between image quality and turbidity and image quality and the resolution of stereo system may be derived respectively.

A system that measures size distribution and spatial profile of phytoplankton has been developed. The phytoplankton can be measured by the system even though the other suspended matters such as inorganic particles and zooplankton exist. This system consists of a laser, a signal processor, and an optical sensor unit. To transmit the light among these, optical fibers are employed. When the phytoplankton in the water flow is irradiated by a laser, chlorophyll-a is excited and emits fluorescence pulse. This pulse is measured as a pulse height distribution of fluorescence. The size distributions of the phytoplankton can be obtained from the computational processing of the pulse height distribution. In the field where multiple plankton species exist, this system allows the size distribution of phytoplankton to be acquired without water sampling. Author (NASDA)

A new phase of ocean research can be expected by making a practical application of a distributed optical fiber sensor to ocean temperature measurement. The distributed optical fiber sensor has been developed for the purpose of continuous measurement of vertical temperature profile in the ocean. The new type of sensor cable, in which the optical fiber of going and returning configuration is encapsulated, was designed and the test cable was fabricated. Experimental measurement was conducted in the Toyama Bay for 16 days from July to August in 1990. In order to estimate the accuracy of the optical fiber sensor, a CTD (conductivity, temperature, and depth) meter was used as a standard instrument. Temperature accuracy at a successive depth spatial interval of 1 m was analyzed. In a representative case, by applying the proposed correction technique to the new sensor system, the accuracy of the ocean temperature spatial profile measurements has increased by about 30 percent compared with non-corrected profile and the average value of the accuracy index proposed for the estimation of the distributed temperature measurements turned out to be about 0.43 C. To understand marine ecosystem structure, it is necessary to know marine organism population. Since zooplankton is the secondary producer in the ocean and is a basic link in the food chain, it is important to know the spatial distribution and temporal variation of zooplankton. For this purpose, zooplankton should be collected frequently at various points. Then, these samples should be identified and counted. For rapid processing of many samples, the automatic classification and counting system has been developed. Features, including sizes, extracted from digital images of plankton for classification are used. Geometric features (for example, maximum length, area, and perimeter of plankton) are extracted as numerical values from images of some samples for one taxonomic group of plankton. The geometric features and non-dimensional features constitute the feature vector and it is taken as a specific characteristic of that group. The accuracy of classification to taxonomic groups of zooplankton depends greatly on image processing and the selection of features. Optimum features for classification with the interclass variance and the interclass variance of the features are found. Effective techniques for the classification are selected between the discriminant analysis and the neural network. The developed classification system consists of microscope, TV (Television) camera, magneto-optical disk, image processor, engineering workstation (EWS), and file server with Ethernet. Images are obtained with the TV camera attached to the microscope. They are digitized and processed through binarization. The EWS is used for extraction of features, classification, and counting of zooplankton. Author (NASDA)

In this paper, the optical attenuation coefficient and the sea temperature profile measured by Ocean Lidar (OLIDAR) are presented. A concurrent Raman scattering signal is used as a calibrating signal for reducing the influence of the random sea surface. From the return signal, the backscattering coefficient, which is about 0.11 in this area, is obtained. The temperature profile of the sea is extracted from the Raman spectrum with different depths detected using the OLIDAR system. The accuracy of temperature measurement is 0.5-1.0 C in-situ, and the depth of detection is about three attenuation lengths with +/- 1.5 m resolution.

An overview of the algorithms of Monte-Carlo simulations used for processing ocean color remotely sensed data is derived and a systematic study via Monte-Carlo simulations are carried out with varying chlorophyll concentrations, commonly encountered in oceanic waters, for the main wavelengths involved in the ocean color remote sensing, and also for various atmospheric turbidities (allowing the ocean to be seen from space,

however). The particularly geometrical conditions (sun angle and viewing angle) considered are those typical of a satellite-borne ocean color sensor operated on a sun synchronous polar orbit. The possible variations of the geometrical factor Q (theta, phi, theta(sub O)) along the track and within the swath (+/- 45 deg) are predicted for various waters. When the algorithms are used to process the ocean color signals and derive the pigment (chlorophyll, C) concentration, the factor f (irradiance ratio/backscattering coefficient/sum of backscattering and absorption coefficients) and Q geometrical factors generally interfere via their ratio of f/Q. Because of similar trends of f and Q variation, their ratio is less varying. Since these residual variations are predictable, iterative schemes can be imagined to improve the accuracy of the computations leading to the pigment concentration from the ocean color remotely sensed data.

In order to develop the data reduction and pigment retrieval algorithms from remote sensing data it is imperative to adopt a sort of simulation of radiative transfer processes and related bio-optical properties. This paper deals primarily with the radiative transfer simulation using numerical techniques. Remote sensing techniques are used for deriving boundary conditions for simulation of radiative transfer processes. The ocean waters are considered to be partially stratified and the optical properties are not homogeneous in the vertical direction. The influence of factors concerned with the heterogeneous environment is found to be considerable. The simulation study included the influence of fluorescence on radiative processes. The factors concerned with horizontal spatial variability needed greater attention and thus, demonstrated the gaps and inconsistencies in the existing bio-optical models. The results are compared with in-situ radiometric observations as well as airborne six channel ocean color radiometer data. A detailed analysis of optical data along with biochemical parameters provided bio-optical models for pigment estimation. The absorption coefficients calculated based on water constituents concentration helped in numerical simulation of radiative transfer processes.

A method to estimate the extinction coefficient, a fundamental parameter for marine optics, using particle size, density, and transmittance has been developed. It is assumed that particles are spherical-shaped suspended matter and polygonal particles are spherical with an equivalent volume. In case of different sized particles, the extinction coefficient is calculated for each particle size that is individually estimated and summed up for all sizes after discriminating by size. A numerical method for calculating a multiple volume scattering function has been developed, assuming that primary scattering is caused by the cleanest sea water. The secondary volume scattering function was calculated by integration in all directions for particles which scattered twice. The second order volume scattering function is the sum of the secondary volume scattering function and the primary scattering function. The higher order volume scattering functions can be calculated by repeating the same procedures. This newly developed parameter could be a strong tool for marine optics analysis.

The ocean color sensor SeaWiFS (Sea Wide-Field Sensor) on the SeaStar satellite is scheduled to be launched in the Fall of 1993. Studies are now under way to develop a new atmospheric correction algorithm to process the imagery. SeaWiFS will have significantly higher radiometric sensitivity than CZCS (Coastal Zone Color Scanner), and because of this the CZCS algorithm is not accurate enough to provide a correction that will enable utilization of the full increases in sensitivity. The goal of the correction is that the atmospheric radiance be removed with an error that is no more than the noise equivalent spectral radiance of the sensor. The specific plans for the SeaWiFS correction algorithm are described. The discussion centers on a modification of the CZCS algorithm to account for the interaction between Rayleigh and aerosol scattering. However, other requirements such as the need for the surface wind speed and surface atmospheric pressure are discussed. Author (NASDA)

DISTRIBUTION OF MINERAL AEROSOLS OVER THE NORTH PACIFIC **c43**
Mitsuo Uematsu and Sei-Ichi Saitou (Japan Weather Association, Tokyo.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 1 25 Aug. 1992 p 471-475 (For primary document see N94-11894 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

In this paper, temporal and spatial variations of atmospheric dust concentration over the North Pacific are compared with the monthly composites of aerosol radiance around Japan. The atmospheric dust events observed by the aerosol sampling at Sapporo, Japan and Vladivostok, CIS (Common-wealth of Independent States) are also determined by the satellite images from NOAA and GMS (Geostationary Meteorological Satellite). From the Level 3 CZCS (Coastal Zone Color Scanner) products in the NASA video browse discs, the images in every spring (April and May) show high values over the Sea of Japan, the east China Sea, and the western North Pacific in the mid-latitude band (20 deg N to 40 deg N). This distribution pattern agrees well with the results from the consecutive measurements of mineral aerosol concentrations and their probability and travel time maps calculated based on the back air trajectory analysis during the Bai (Asian dust storm) events observed at the island stations in the central North Pacific. Pronounced Bai events recognized by the satellite images of GMS and NOAA are observed at both the sampling stations in late April, 1990 and May, 1991. The results of chemical analysis confirm the dust clouds from the satellite images. Author (NASDA)

This paper discusses a possible climate change resulting from modification of cloud microphysics through interacting low level clouds with aerosols, which will increase as a result of global scale pollution. Recent study has shown several examples of large scale contamination of low level clouds due to increasing anthropogenic SO2 emission and it is pointed out that such cloud modification may partly compensate for the global warming. Two cases of anthropogenic cloud modification are studied to assess the magnitude of their climate effects. Semi-empirical relationships between effective droplet radius and cloud water path for marine stratocumulus clouds off California and for cumulus clouds over Amazon area are determined. Global average surface temperature changes, associated with the cloud modification are estimated by a simple assumption of climatic sensitivity of 0.7 K (W/sq m)(exp -1) and that 1 percent of cloud cover undergoes cloud modification. Since the increase of aerosol concentration is much lower for the maritime cloud case than the Amazon case, the cooling effect will dominate over the heating effect in the global scale average. This paper describes two algorithms for aerosol retrieval. One involves vertical structure inversion, which provides the profile of atmospheric extinction from the ADEOS (Advanced Earth Observing Satellite)-ILAS (Improved Limb Atmospheric Spectrometer) data, and the iterative routine in respect of comparison of the simulated results with the measurements in order to estimate the optical thickness of stratospheric aerosols. The other is an algorithm to set up an appropriate aerosol model suitable for the NIMBUS-7 CZCS (Coastal Zone Color Scanner) image of interest to pursue an accurate atmospheric correction. Twenty NOAA-AVHRR (Advanced Very High Resolution Radiometer) data sets between March and July 1990 were analyzed to see the dispersion of volcanic ash clouds from Mt. Sakurajima in Kyushu Island, Japan, in conjunction with the ground observation. The extension of ash clouds was found to be more than 100 km in some cases when the activity of the volcano is relatively high. The pattern of the horizontal diffusion of the ash clouds was found to be most sensitive to the vertical shear of the winds around 1-3 km above the sea level. For the extraction of volcanic clouds, multi-level slice classification using AVHRR Channel 3 and 4 is found to be useful. False color composites (Channel 3, 4, and 5) are also simple and useful. The radiances impinging on a ground target point in mountainous terrain can be divided into three radiance components, namely: (1) the direct solar radiance component; (2) the diffusely transmitted radiance component by the atmosphere; and (3) the diffusely reflected radiance by adjacent slopes. These radiances are evaluated quantitatively for various sun positions and target slope orientations by using the backward Monte Carlo method. The evaluation of the adjacency effect due to multiple reflections of light by surrounding slopes for realistic topographic conditions is, for the first time, in this study. Author (NASDA)

For a precise atmospheric correction on the ocean color data near the coastal region, a numerical method of evaluating the upwelling radiation at the top of the atmosphere bounded by the two half semi-infinite surfaces is developed. The present method would be able to apply to the case of hazy atmosphere and/or large albedo of the surface. Author (NASDA)

Because oil spill incidents, both accidental and intentional, will likely become more frequent in the future, it is of grave importance to be able to determine the oil spill floatation courses in the oceans. Taking into consideration that most Japanese tankers shuttling between Japan and the Persian Gulf pass through the surrounding waters of the Okinawa Islands, research has been conducted to determine the course that oil spills originating in the lower latitudes of the western Pacific Ocean will take. The research results are based on the findings of: (1) drift bottles; (2) GEK (Geomagnetic Electrokinetograph); (3) routes of drifting ships; (4) distribution of wind speed in the north Pacific Ocean; (5) flotation of Pumice stones; and (6) other related findings. Calculations of isotherms lengths at the NOAA AVHRR (Advanced Very High Resolution Radiometer) infrared images for the Japan sea from April 1990 provide experimental evidence of the fractal properties of the SST (Sea Surface Temperature) patterns as being tracers of sea mesoscale turbulence. The isotherms fractal dimension is found to be 1.27 plus or minus 0.07 for space scales from at least 4 km to approximately 120 km. Estimation of sequences of mass exponents shows that the SST patterns exhibit rather monofractal than multifractal behavior. Analysis of the AVHRR images shows that self-similar turbulent structures-chains of vortices consist of vortex pairs and anticyclonic eddies. Their evolution and possible mechanism of formation are discussed. Author (NASDA)

This paper describes a geostrophic transport field in NPIW (North Pacific Intermediate Water). The circulation pattern of the NPIW became clear using Levitus's climatological data as a data source for the inverse model. NPIW circulation is composed of four main branches. Three of them recirculate in the sub-tropical region and the other branch recirculates in sub-polar region. The most eastward going branch in the sub-tropical region continues to the eastward flow of salinity minimum layer in the lower latitude, of which specific volume anomaly is 150 cl/ton, but main circulation of NPIW is confined to the region of higher latitude than 25 deg N and will coincide with the distribution of NPIW (i.e., the salinity minimum of 125 cl/ton). The source region of NPIW may be identified around the sub-polar region adjacent to the Sea of Okhotsk and from the western end of the disturbed area. The inverse model used in this study did not include boundary areas, so the heat and volume transferred across the Pacific were not clear. Also, mesh size was too coarse to identify the process of NPIW change along the easternmost branch and to distinguish waters from the Sea of Okhotsk and those from the western region of the disturbed area. The mid-depth circulation of the Shikoku basin was measured using twelve neutral SOFAR (Sound Fixing and Ranging) floats released at five layers ranging from 1,000 m to 4,000 m. Some trajectories of the floats tracked from April 1988 to January 1991 indicate the clockwise circulation associated with the dominant warm water mass in the Shikoku basin. The mean drift speed was 7.6 cm/s above 1,500 m depth and 3.2 cm/s under 2,000 m. The eddy diffusivities were 10(exp 6) to 10(exp 7) sq cm/s and the values decreased with depth. Author (NASDA)

A coastal upwelling front parallel to the coast and identifiable up to a depth of 75 m was observed between 12.5 and 16 deg N along the eastern Arabian Sea in September, 1987 from closely spaced digital BT (Brightness Temperature) data. With a north-south slope in the thermocline, the front has a temperature gradient of about 6 C over a distance of 30-50 km and appears to be closer to the coast on the northern side than the southern side. Information derived from data during July, 1987 shows no such front at a depth of up to 30 m at this location. An estimate based on the positions of isotherms indicates offshore movement of surface water at a rate of about 1-2 km/day from July to September. Vertical velocities computed in the frontal region using the conservation equation of temperature show an average value of -2.77 times 10(exp -2) cm/sec which is indicative of upwelling. A comparison of offshore volume transport and a temperature anomaly near the coast did not show good correlation. These observations suggest that upwelling along this coast propagates from south to north in the form of a coastally trapped wave. Author (NASDA)

The sea surface temperature anomalies over the various study areas, namely, the northern, western, central, eastern, and southern Arabian Sea areas have been studied for the period 1948-1972. There were about 105, 87, 2, 74, and 87 sea surface temperature anomalies for the above regions, respectively. An analysis has shown that most of the short duration anomalies (i.e., anomalies with periods less than four months) are driven by the surface heat fluxes. The medium duration anomalies (i.e., anomalies with periods between five and ten months) are driven by advection (both horizontal and vertical) and other oceanic processes. The causative factor of large duration anomalies (with periods greater than ten months) cannot be pinpointed to any particular factor. Further analysis has shown that the sea surface anomalies are well correlated to the anomalies of air temperature and latent heat flux values; whereas, they are least correlated to the anomalies of wind stress and net radiation values, except over the northern Arabian Sea where they are negatively and significantly correlated with the net radiation values. In the western part of Indonesia, January is the beginning of rainy season. This season is caused by the pressure difference between Asia (high pressured) and Australia (low pressured), in which wet air masses flow from the Indian Ocean to the eastern part of West Java, producing a very high intensity of precipitation in the northern part of Central Java. This precipitation influences flooding in Semarang, because of the amount of surplus soil water greater than Water Holding Capacity (WHC). Author (NASDA)

The volumes of the warm water flowing into the western Pacific Warm Pool through the MC (Mindanao Current) are estimated on the basis of the existing CTD (conductivity, temperature, and depth) data from western Pacific cruises of R/V (Research Vessel) Science 1 of Academia Sinica Institute of Oceanology in the fall of the recent four years and recent results from other scientists upon the western Pacific region are analyzed to assure the idea that NEC (North Equatorial Current) and MC may be important in the formation and seasonal and annual variation of the Pacific Warm Pool. It can be seen that despite the temporal variation of the surface heat flux, the convergence of the main currents in this area such as the MC and SEC (Southern Equatorial Current) may be important in the variation of the Warm Pool and that the warm water transport in the NEC may be important in the warm water balance in the Warm Pool area.

The GEOSAT wind data within a 2 deg by 2 deg grid over the North Pacific was analyzed for each month. Then, the monthly GEOSAT wind data was compared with other wind data, i.e., ship wind (COADS (Comprehensive Ocean Atmosphere Data Set)), satellite wind (SSM/I (Special Sensor Microwave Imager)), and model output wind (ECMWF (European Center for Medium Range Weather Forecast)) data. Cross correlation coefficients between them are fairy high, and show remarkable seasonal variation such that those show higher values in winter and lower values in summer. The similarity between GEOSAT and SSM/I wind data is remarkable.

Annual and interannual variability of upper ocean circulation is primarily caused by surface wind, yet little is known about the surface wind field because of difficulties in making adequately sampled in-situ wind observations. Since July 1987, the Remote Sensing Systems (RSS) routinely computes from first principles the wind speed from the intensity of microwave radiation emitted at the ocean surface by the Special Sensor Microwave Imager (SSM/I). Annual and interannual variations of monthly-mean RSS SSM/I 10 m height wind speed were analyzed during the July 1987 to December 1990 period over selected regions and at selected sites of the Pacific Ocean. The annual cycle amplitude and annual mean value were not the same in the northern and southern hemispheres. No multi-year trend was observed. The largest interannual variations were associated with the 1987 El Nino and 1988 La Nina, and only in the equatorial zone.

The wave-coming direction is of vital concern to ship's navigator, especially in rough seas. Wave crests and troughs are clearly visible in the satellite imagery. Some information on wave features are taken from such remotely sensed data. On 22 June 1987, LANDSAT TM (Thematic Mapper) image was taken over the coastal region of Miyagi, Japan, where storm-driven large waves were prevailing. Wave crests appear to be discontinuous and short offshore and become less broken and longer towards the shore. In this paper, the evolution of wave crests is studied by an FFT (Fast Fourier Transform) technique and inspection of computer processed imageries. Some interesting facts directly observed or derived from the TM images are as follows: (1) depths at which shoaling effects begin to appear can be determined; (2) lengths to which wave crest grow as they continue to move shoreward can be estimated; and (3) wave convergence zones where the wave crests are broken can be specified and monitored.

OBSERVATIONS OF EDDY FIELDS IN THE NORTHWEST PACIFIC BY GEOSAT ALTIMETRY c43
Jun Suwa, Akira Mukaida, and Yasuhiro Sugimori *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 576-581 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The purpose of this study is to estimate the space and time characteristics of the sea level variability in the Northwest Pacific, including the Kuroshio extension region, from November 1986 to December 1987, based on the GEOSAT data. A collinear differences method was applied to only data along ascending passes. In processing the raw altimeter data, all the environmental corrections were applied. A mean profile of each pass is constructed from each individual profile to eliminate time-independent effects of the gravity field and quasi-permanent mean circulations. Orbit error can be removed by substructing the quadratic trend from each pass using a least square fit. The orbit error removal is performed using the passes with a length of about 2,000 km. Thus, any oceanic temporal variabilities of wavelengths 2,000 km or longer are significantly altered, while only those of wavelengths shorter than 1,000 km remain, and then these data are interpolated to a 0.5 degrees latitude and longitude grid. Sea height variability can be estimated simply by computing the standard deviation at each grid point. The method to calculate the wave propagation speed and the equations used for the computation are presented.

Using GEOSAT altimeter data, sea level variability are analyzed in the equatorial Pacific Ocean during November 1986 to February 1989. SST (Sea Surface Temperature) from NOAA/AVHRR (Advanced Very High Resolution Radiometer) and temperature from the ATLAS (Atmospheric Laboratory for Application and Science) buoy array deployed by PMEL (Pacific Marine Environmental Laboratory) are also analyzed over the same area and the same period, respectively. Positive SLA (Sea Level Anomaly) and SSTA (SST Anomaly) were formed near 160 deg W on the equator and then propagated eastward from the end of 1986 through the beginning of 1987, respectively. But time lag was found for about 20 days of SLA precedence. Variation of SLA corresponds with that of the thermocline depth with the correlation coefficient of 0.7. Author (NASDA)

Altimeter measurements of wind speed, significant wave height, and sea level are based on empirical Geophysical Model Functions (GMF) relating satellite Level 1 data products to oceanographic parameters of interest. However, analysis of altimeter measurements show that the Level 1 data (i.e., the radar cross section, the travel time of the return pulse and the wave form) are affected by oceanographic factors, particularly the wave age, which are not directly accounted for in the GMFs. As a result, satellite measurements of sea level height and wind speed contain systematic errors correlated with the wave age. Such errors would introduce geographically and seasonally related biases into satellite-based global maps. Hence, new GMFs which account for effects of the wave age are desirable. In the present work, the improved GMFs developed at Jet Propulsion Laboratory (JPL) are described. Author (NASDA)

The analysis of altimetry measurements along repeated satellite ground tracks provides an excellent way of determining temporal variability in the sea surface height. A new unified analysis method has been proposed for the simultaneous estimation of orbit error, mean sea surface height, and residual sea surface heights (variability) with respect to each pass. All passes are treated in exactly the same way; the consequent rank or datum defect in the model can be overcome by appending a minimal set of conditions, chosen either to give no overall distortion of the orbits or otherwise a best fit to a reference profile, such as the geoid. Gaps in the altimeter data are easily accommodated. Numerical results of the simultaneous method are shown using data from the GEOSAT Exact Repeat Mission (ERM). Some consideration is given to the choice of a suitable radial orbit error model. The results indicate that for removing the time-varying portion of the orbit error, a sinusoid model is the most appropriate over a one revolution cycle. Author (NASDA)

The Southern Ocean is known to have a vigorous eddy field with large geographical variations. However, quantitative measurements of these eddies have been limited by the difficulty and expense in maintaining long term observational arrays. This study uses GEOSAT satellite altimeter data in the Southern Ocean to resolve anisotropic eddy kinetic energy and horizontal eddy momentum flux on fine space and time scales. The resultant eddy variability ellipses compare favorably with surface drifter data in the Tasman Sea, and with in-situ current meter observations. The complex spatial distribution of surface eddy momentum flux is strongly influenced by bottom topography, and the position of the mean current. In general, the horizontal eddy fluxes tend to converge momentum towards the defined mean flow, with limited regions of divergence. In regard to the momentum balance, the results show the circumpolar average of horizontal eddy momentum flux from transient eddies to be an order of magnitude too small and in the wrong direction to directly balance the eastward momentum input by the wind. The altimeter data cannot resolve the standing eddy component, and transient and standing eddies may still be important in transporting momentum downwards, to be balanced by bottom friction and topographic form drag. The OGCM (Tropical Pacific Ocean General Circulation Model) simulated surface dynamic height is compared with the sea surface height derived from the GEOSAT Exact Repeat Mission. Good agreement was found between the GEOSAT data and OGCM simulation in describing an equatorial Kelvin wave pulse generated by westerly wind bursts in December 1986, 1987 El Nino, and 1988 La Nina. Both data sets are validated against in-situ sea level measurements at 12 stations in the equatorial Pacific Ocean, and found to be in good agreement with the in-situ data with correlation coefficients of approximately 0.7. The standard deviations of the GEOSAT data and OGCM simulation are 7.7 cm and 7.1 cm, which capture 79 percent and 72 percent of the variance observed by in-situ measurements (the standard deviation of the in-situ data is .8 cm), respectively. The model sensitivity experiment on two different wind products showed that the FSU (Florida State University) winds are about 30 percent stronger than the winds from European Center for Medium Range Weather Forecast (ECMWF), and that these differences in surface wind forcing produce significantly different OGCM simulated dynamic height as compared with the in-situ and GEOSAT data. The pseudo-magnetic anomaly in NFB (North Fuji Basin) was calculated from GEOS-3, SEASAT, and GEOSAT altimetric gravity data by the assumption that both gravity and magnetic anomalies were caused by a certain common source material. The distribution of the calculated pseudo-magnetic anomaly is compared with the observed one in order to verify the parameters characterizing the geomagnetic structure in this area. The pattern of positive and negative magnetic anomaly coincides well with that of the pseudo-magnetic anomaly in the southern part of the NFB where the opening has been in progress since 0.7 MaBP; whereas, these patterns are quite different from each other in the northwestern part of NFB where the opening occurred from 10 MaBP to 3 MaBP. From November 1986 to January 1989, sea level variations in the tropical Pacific (30 deg S to 30 deg N) have been derived from GEOSAT ERM (Exact Repeat Mission) data using methods of both crossover and collinear analysis. The Principal Oscillation Pattern (POP) analysis is applied to analyze the altimetrically derived sea level variations in order to identify the dominant patterns present in the observational field. One dominant POP pair describes the eastward propagating equatorial Kelvin waves with the period of 110 days. This Kelvin mode is considered as a random force acting on the coupled ocean-atmosphere system. On the other hand, an individual Kelvin wave is not the precursor of the El Nino event. However, strong Kelvin waves can very likely result in an El Nino event. The second POP pair delineates the north-south oscillation of the sea level between two zonal bands 4 deg N to 10 deg N and 2 deg S to 4 deg N with a period of one year. This oscillation pattern results from the meridional Ekman transports of the upper layer associated with the seasonal migration of the Intertropical Convergence Zone (ITCZ). This meridional oscillation in the annual cycle is in phase with the onset and decay of the 1986-1987 El Nino event. Furthermore, the upper layer seems to move more rapidly from the equator to the northern hemisphere (five months) than from the northern hemisphere to the equator (seven months). Author (NASDA)

Movement of sea surface height anomalies can be studied using GEOSAT altimetry data and may provide useful new information on large scale ocean circulation. A cross-correlation analysis of anomaly maps of the north-east Pacific (approximately 0 deg N to 60 deg N, 110 deg W to 160 deg W) compiled from 48 of the 17 day cycles of GEOSAT data, mapped mean drift speeds of 0.5 to 3.5 cm/s for the 2.2 year period with a spatial resolution of 600 km. The velocity variation with latitude is consistent with the motion of baroclinic Rossby waves and advection by the large scale ocean circulation. Author (NASDA)

Fluctuations of the Sea Surface Dynamic Topography (SSDT) are studied for the Kuroshio extension region during the first year of the GEOSAT Exact Repeat Mission (ERM) in 1986-1987. A set of successive maps of the temporal fluctuation of SSDT derived from the GEOSAT altimetry data shows that a pair of cyclonic disturbances moved westward at a fairly constant speed over 200 days and finally coalesced into a stronger single cyclonic disturbance. In the field of approximated total SSDT (the climatological mean SSDT plus the present temporal fluctuation SSDT), the same phenomenon can be understood as a westward propagation of a southward meander of the Kuroshio extension followed by pinching-off of the amplified meander accompanied with formation of a cyclonic eddy south to the stream. Those fluctuations found in the approximated SSDT field are confirmed by conventional oceanographic observation data and NOAA Advanced Very High Resolution Radiometer (AVHRR) imageries, although the latter are fragmental. This study presents a method that estimates the mean surface height field in a boundary current region from residual height data of altimetric observations. Applying this method to the Kuroshio Extension (KE) region revealed that the mean and the instantaneous height fields estimated in this manner compared well with the available hydrographic data and the Sea Surface Temperature (SST) patterns from NOAA satellites. Based on 2.5 years of the GEOSAT Exact Repeat Mission (ERM) data, it was found that the mean surface height difference across the KE attains its maximum around 146 deg E between the two quasi-stationary meanders, and its decrease thereafter is mainly due to large-scale recirculations on the southern side of the KE. Propagation of mesoscale fluctuations in the height fields is generally westward except for the upstream region of the KE. Effects of deep mean flow and baroclinic shear are found to be important in explaining the observed propagation speeds. In the upstream region of 141 deg E and 154 deg E, annual variations in the surface height difference across the KE (delta h) have a September maximum with an average amplitude of 0.2 m. For large-scale interannual fluctuations, anomalies in delta h are found to be significantly correlated with those of the current axis positions: a larger surface height difference corresponds to a more northerly position of the KE. The interannual changes in delta h are possibly related to the ENSO (El Nino and Southern Oscillation) event during 1986 to 1987 in the low-latitude Pacific Ocean. Author (NASDA)

Data collected by the Scanning Multichannel Microwave Radiometer (SMMR), flown on the NIMBUS-7 spacecraft have been analyzed to provide spatial and temporal coverage of sea ice in the polar regions from October 28, 1978, through August 20, 1987. The region selected for discussion here is of particular interest to the Pacific-rim countries. This region includes the Seas of Japan and Okhotsk, as well as the Bering Sea and, in the South Pacific, the Amundsen, Bellingshausen, and Ross Seas. Monthly averages of the sea ice concentrations in all of these seas are presented, as are time series of single-day records, obtained every other day on the average, of the area enclosed by the ice boundaries, the areal coverage of ocean by ice, and the open water area within the ice boundaries. Interannual variability and the 8.8 year trends are also described, as well as the contribution of the Pacific-rim regions to the overall negative trend of ice coverage in the Arctic, and the lack of trend in the Antarctic, during this period. Numerical experiments have been carried out to investigate the formation process and the properties of deep convection in the Weddell Sea. The thermobaric effect, i.e., an increase in value of the thermal expansion coefficient of sea water with pressure (depth) at low temperatures, makes the mixed layer unstable and deep convection catastrophically occurs as a 'thermal' plume. As the colder (less-saline) mixed-layer water intrudes into the warmer (more-saline) underlying layer, the thermocline (halocline) at the base of the mixed layer gradually ascends to disappear at the sea surface. It takes only a few days for the thermocline (halocline) to disappear if the sea surface is not covered with ice. On the other hand, it takes more than 20 days, owing to the reduction of cooling rate, if the sea surface is covered with ice. The latter implies that the vertical transport of heat and materials will be modified in the interannual time scale by such a moderate overturning process. Author (NASDA)

The Seasonal Ice Zone Experiment (SIZEX) 1992 was a post-launch ERS-1 field experiment carried out in the Barents Sea in March 1992. The overall objective is to estimate and validate ice parameters derived from ERS-1 SAR (Synthetic Aperture Radar) such as ice edge location, ice motion, ice concentration, and ice type classification. The SAR images provide a promising tool to classify ice regions based on different ice characteristics such as floe size, leads, ice types, shear zones, wave penetration in the ice edge region, and areas of new-frozen ice. Mass balance in the Shirase Glacier drainage basin in the Queen Maud Land ice sheet, East Antarctica, has been studied using the accumulated data of snow stake measurements, density, flow rate of ice, and ice thickness, and could suggest a small negative value with a large error estimated more than 30 percent. Due to the most uncertainty of snow accumulation in the drainage area for mass balance calculation, the regional snow accumulation measured will be compared with the amount of snow deposition estimated by satellite image data and discussed on mass balance trends of Shirase Glacier drainage basin in the Antarctic Ice Sheet. In the polar regions, ocean and land are covered by ice of different thickness. Due to the intrusion of ocean water in the coastal areas, the salinity of ice changes. In the present paper, detailed numerical calculations have been carried out to study the microwave remote sensing response over various models representative of polar regions consisting of ice covering of different physical characteristics. Effect of the physical, chemical, and electrical characteristics of the ice and ice thickness on the radiometer response has been found to be significant. Author (NASDA)

Phytoplankton size spectrum in Hunka Bay is measured using an optical fiber sensor developed by Kakui et al. The time variation of size spectra throughout a year is also presented. The major feature is that the phytoplankton that are 40-45 micrometers in diameter dominate in the spring bloom, which corresponds to chain form Chaetoceros. In other seasons, remarkable phytoplankton does not appear. With regard to zooplankton, the microzooplankton population peak coincides with the phytoplankton blooming period, while net zooplankton population grow after the termination of spring bloom. A surface water monitoring system was developed to continuously measure water temperature, conductivity, dissolved oxygen, fluorescence intensity, and plankton size composition in the sea surface layer. The system consists of three units, sensors unit, navigation information unit, and control unit. Water pumped up from a haul intake is led into the sensors unit to measure the variables mentioned above as well as the flow rate of water running through the system. Analog signals from the sensors unit and digital data from navigation information are transferred into the control unit at one minute intervals. These data are displayed and stored in a computer system. The system is expected to provide useful data for the sea-truth observations in satellite observing area. Field experiments made in various areas revealed the usefulness of this system for detecting fine scale spatial variation of the oceanographic variables. The relation between the sea surface temperature observed by this system and the thermal image from NOAA-11 is examined. Author (NASDA)

Primary productivity within the euphotic zone was measured with C-13 method and daily primary production was estimated. Daily primary production was in the range of 372 to 633 mgC(m sup -2)(d sup -1) in the spring and 384 to 2109 mgC(m sup -2)(d sup -1) in the summer. Excluding the largest one, the values in the summer were within the range of those in spring. To cancel the difference of light condition during observation, light utilization efficiency and quantum yield were calculated. From these results, the factors affecting primary production are discussed. Author (NASDA)

Three dimensional fluorescence matrices (EEM (Excitation-Emission Matrix)) has been obtained for characterizing Dissolved Organic Matters (DOM) in the ocean. DOM was concentrated from the filtered sea water by using the gel adsorption chromatography, where ion-exchange gel or hydrophobic gel was used. EEMs of the concentrated sea water sampled at Suruga Bay reveal at least four characteristic fluorophores. Two of them are suggested to be a humic acid and a carbohydrate. Author (NASDA)

Biomass, chemical composition, and production rate of phytoplankton populations are studied at Kinu-ura Bay, Japan, which is semi-closed eutrophic bay. The study took place during the rainy season from late May to early July in 1983, at intervals from one to five days. Considerable amounts of nutrients were frequently supplied from rivers into the surface layer of the bay in the experimental period. These appeared to be a major direct nutrient source for phytoplankton blooms in this season. Renewal of water mass with frequent river influx largely affected occurrence and disappearance of phytoplankton bloom. The protein/carbohydrate ratio of particulate matter at the surface layer was generally greater than or equal to three, which indicated high growth activities of phytoplankton populations at the surface layer throughout this period. Mean and total production rate for the experimental period were about 2 and 90 gC(m sup -2)(d sup -1), respectively. The importance of the production in the rainy season to an annual production is suggested by this study. Author (NASDA)

VARIATION OF THE PHOTOSYNTHETIC PRODUCTS IN THE REGIONAL UPWELLING AREA AROUND THE IZU ISLANDS, JAPAN c51

Takeo Hama *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 698-703 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

This study is carried out to assess the relation between the photosynthetic products and nutrient availability of the phytoplankton population. A combined C-13 tracer and Gas Chromatography-Mass Spectrometry (GC-MS) method was applied to determine the composition of photosynthetic products inside and outside of regional upwelling waters around the Izu Islands, Japan. This method can measure the monosaccharide and amino acid composition of carbohydrate and protein/amino acid of photosynthetic products, respectively. Production rate of protein/amino acid (sum of the production rates of 12 amino acids) was highest in the nutrient-rich 'maturing' upwelling water, where higher concentrations of nutrients were measured than in the non-upwelling and nutrient-depleted 'aged' upwelling waters. Production rate of carbohydrate (sum of the production rates of eight monosaccharides), on the other hand, showed the highest value in the 'aged' upwelling water and this was exclusively due to the high production rate of glucose; the production rate of glucose accounted for 90 percent of the total carbohydrate production, whereas glucose accounted for 50 percent in 'maturing' upwelling water. These results demonstrated that composition of photosynthetic products significantly varied through the 'aging' of upwelling, probably due to the change in the nutrient availability. Author (NASDA)

In Jan. 1985, the NOAA created the Ocean Products Center (OPC) to formalize the realization that marine data sets are scientifically useful only when quality controlled and then integrated with relative measurements to provide multidisciplinary information. The OPC is a unique cooperative center housing elements of the National Weather Service, National Ocean Service, and the National Environmental Satellite, Data, and Information Service. The contributing offices work closely together to provide a tightly coupled, integrated approach of end-to-end quality control and distribution of forecasts, analyses, observation, data products, and imagery. This body of real-time, quality controlled in situ data, satellite remotely-sensed data and model output is made available through the OPC-managed NOAA Ocean Communications Network (NOCN) to users world-wide. This paper describes the end-to-end quality control of ocean data in the real-time environment conducted at OPC. Author (NASDA)

In order to analyze remote sensing data from microwave radar on a satellite, it is necessary to remove the effects of microwave attenuation and reflection caused by precipitation. Generally, the attenuation and reflective coefficients depend on precipitation rate, kinds of precipitation, raindrop/snowflake size-distributions, and temperature. In the case of satellite observation, precipitation structure models from snowflake to raindrop along a slant path have to be considered. In this paper, one of the precipitation structure models and its evaluated parameters using ETS-2 (Engineering Test Satellite-2) satellite experiment data at Kashima, Japan in 1977 is reviewed, and a trial was made to simulate the radar echo observed from a meteorological satellite based upon the calculated precipitation model. This kind of approach will be useful in performing a feasibility study of active satellite radar and to design a meteorological satellite system. Author (NASDA)

The Joint Ice Center (JIC) is responsible for producing global, regional, and local ice analyses and forecasts for the Arctic, Antarctic, and the Great Lakes. Traditional hard copy/grease pencil methods of manual analysis have been the principal mode of ice analysis until recently. The JIC now has a prototype Digital Ice Analysis and Forecast System (DIFAS-version 0) that has been used to demonstrate the applicability of computer science as a tool for the interactive production of ice analyses. This paper discusses the suite of products produced at the JIC, the interim use of manual drafting techniques blended with DIFAS-0, and the future plans for integration of interactive digital techniques as well as the computer systems necessary to meet these goals. After a presentation of the METEOSAT first generation program, the new missions foreseen for the second generation of METEOSAT are given. They include a continuity of Earth imaging with improved performances and a sounding capability necessary to monitor instability processes. The paper presents the new generation instrument SEVIRI (Spinning Enhanced Visible and Infrared Imager) with its unique features for sounding from a spinning geostationary spacecraft. The instrument spatial, temporal, radiometric, and spectral resolutions will be shown to fit the rapid development of weather prediction numerical models. Emphasis is on instrument characteristics directly relevant to meteorological applications and corresponding processing, including: (1) convective phenomena evolution monitoring on local scale; (2) wind data and cloud motion vector measurements; and (3) surface data and derivation of thermodynamic surface temperature, etc. The conclusion will enlighten the improvements that can be expected from better vertical information at a high repeat cycle. EVALUATING THE SPREAD OF RED SOIL WITH LANDSAT TM DATA IN CORAL REEFS OF OKINAWA MAIN ISLAND, SOUTHWESTERN JAPAN c43

Katsuo Okamoto, Ichirou Yamada, Toshiaki Imagawa, and Michikazu Fukuhara *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 742-747 Prepared in cooperation with Okinawa Prefecture Agricultural Experimental Station, Okinawa, Japan Original contains color illustrations (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The purpose of this paper is to clarify the distribution of red soil which is deposited over the coral reefs at the periphery of Katabaru located on the eastern coast of the northern part of Okinawa Island, by grasping the degree of contamination based on the relationship between the TM (Thematic Mapper) data and the amount of Fe2O3 contained in the red soil. As a result, the facts stated below are revealed: (1) there is a high-correlation between the interchannel ratio of the TM data and the amount of Fe2O3 contained in the red soil; thus, the interchannel ratio is an effective index for analyzing the distribution of the sedimented red soil; (2) the distribution of red soil was estimated using the interchannel ratio of the TM data, and a remarkably large amount of red soil was found to be deposited near the estuary, and other sedimented areas were recognized inside the reef crests and along the coast, as well; and (3) the distribution area of red soil off the coast of Katabaru was almost identical from 1984 to 1989. This is consistent with the fact that large-scale construction work, which involved major topographic alterations to the basins of rivers flowing into this area of the coast, was concentrated in the period up to and including the early 1980's, and that there was only a small number of construction projects after 1984. A special image processing system for satellite remote sensing was developed. The system is provided with many advantages, such as powerful hardware functions, abundant software, high performance to cost ratio, etc. The hardware of the system consists of an image processing board with integrated microcomputer, a tape recorder, an optical disc, a video signal source (TV (Television) camera), a plotter, a paint jet, and an image monitor. The software of the image processing system includes an image data base management system which is a simplified command language to invoke application programs and a library of tens of image processing application programs. The features, configuration, and each part function of the image processing board and detail of the software are outlined.

VALIDATION TEST SYSTEM FOR SEA SURFACE TEMPERATURE DETECTED BY SATELLITES IN MUTSU BAY **c43**

S. Tanba, T. Souma, M. Konda, I. Yoshida, T. Watanabe, R. Yokoyama, Hironori Maejima, and Korehiro Maeda *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 751-756 Prepared in cooperation with NASDA, Tokyo, Japan (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

An accuracy validation test project for the Sea Surface Temperature (SST) estimation by satellite data was undertaken in Mutsu Bay. The sea and air truth data are provided by the four observation systems operated by independent organizations: (1) Mutsu Bay Automatic Buoy System (MBABS); (2) Automatic Meteorological Data Acquisition System (AMeDAS); (3) Sea Surface Temperature Profiler Buoy (SSTPB); and (4) Radio Sonde Observation System (RSOS). The satellite SST is combined with the sea truth SST by MBABS to form match-ups for the validation test. Their temporal and spatial coincidences are guaranteed to be within 30 minutes and one pixel resolution, respectively. The data of AMeDAS, SSTPB, and RSOS can be effectively referred in the error analysis of the SST estimation.

Since May 1989, Hachijo branch of the Tokyo Metropolitan Fisheries Experiment Station has been using satellite imagery and computer technology to get sea surface temperature images of north-west Pacific Ocean to assist the fishermen at Hachijo Island. Hachijo branch can obtain the sea surface temperatures on the ferries' course along the Izu Archipelago and it's eastern area within a one day time interval. It is very difficult to get information about sea surface temperatures of the western area, every day, so infrared images from Geostationary Meteorological Satellite (GMS) are useful in providing the western sea surface temperatures during the early spring when the bonito fishing starts. On March 23, 1990, the range of the temperature front on the ferries' course was from 17 to 19 C, and the position of the front in the image on the line of Izu Archipelago and it's eastern area was almost equal to the position of the temperature front provided by the ferries' observations. The western temperature contour lines could be drawn as the pattern of the Kuroshio which was meandering offshore the southern mainland of Japan.

MEASUREMENT OF THE SEA SURFACE EMISSIVITY **c43**

Masanori Konda, Norihisa Imasato, Katsuya Nishi, and Takashi Toda (Shiga Prefecture Board of Education, Japan.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 762-767 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Sea surface emissivity is determined by observation data analyses, considering surface reflection of atmospheric downward radiation. Radiation balance and other meteorological variables are measured almost throughout a year at the oceanographic observatory tower in Tanabe Bay. It is found that the cool skin on sea surface is disturbed and temperature difference across the cool skin vanishes under the condition of large wind speed over 5 m/s. Reliable emissivity values are computed under a condition such as 0.984 +/- 0.004. Consequently, half of the temperature difference between SST (Sea Surface Temperature) and the temperature retrieved from surface radiation are found to be reduced, in comparison with our results for the case in which we assume the sea surface to be a black body.

EVALUATION OF THE METHOD OF GEOSTROPHIC FLOW USING NOAA-AVHRR DATA **c48**

Masatoshi Akiyama and Yasuhiro Sugimori *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 768-773 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Near surface velocities in the Kuroshio extension area are derived from a single scene of NOAA-6 AVHRR (Advanced Very High Resolution Radiometer) imagery supplementing the satellite observed SST (Sea Surface Temperature) with synchronized hydrographic observations. The geostrophic equation is approximated to derive the surface velocities. The flow field obtained is compared with GEK (Geomagnetic Electrokinetograph) current vectors and also with the geostrophic surface currents. It is found that the geostrophic approximation, used in this study, resolved the salient features of the flow patterns in this region. The fairly good agreement of the approximated geostrophic currents with the GEK and geostrophic currents supports the validity of geostrophic approximation in the regions where the surface topography can be expressed as a function of sea surface temperature. Since the AVHRR infrared images are vulnerable to cloud contamination, the availability of cloud-free sequential-image pairs sometimes occurs as a limitation to obtain surface currents using sequential-image pairs. In such cases, the method presented in this study can be considered as an option.

Further study of NOAA satellite SST (Sea Surface Temperature) measurement has been done based on the Non-Regression Coefficient SST (NRCSST) method presented. Instead of a set of regression coefficients, the NRCSST method requires a brightness temperature ratio (R(sub 54)) of T(sub 5) to T(sub 4) which can be determined from a scatterogram of the brightness temperatures. The method is practiced and demonstrated in the north, east and south of the China Sea. The retrieved SSTs are compared with the ones derived from the MCSST (Multi-Channel SST) algorithm provided by NOAA/NESDIS (National Environmental Satellite, Data, and Information Service). It is shown that both the NRCSST and MCSST methods give the same SST distributions. A main difficulty in the NRCSST method is to determine the ratio R(sub 54) accurately. A complementary method is to make an off-set on one of the brightness temperatures, which may modify the SST output. As an example, the NRCSSTs will be 0.4 K higher than the MCSSTs when the off-set on T(sub 4) is -0.1 K. This result is satisfied since the MCSSTs are normally about 0.5 K lower than the in-situ measurements in the China Sea.

An GCSED (Generalized Cluster Shade Edge Detection) algorithm and a series of post processing techniques are discussed for automatic delineation of mesoscale structure of the ocean on digital IR (infrared) images. The popular derivative based edge operators are shown to be too sensitive to edge fine structure and to weak gradients. The new edge detection algorithm is GCSED method, and it is found to be an excellent edge detector that exhibits the characteristic of fine structure rejection while retaining edge sharpness. This characteristic is highly desirable for analyzing oceanographic satellite images. This procedure is evaluated on an AVHRR (Advanced Very High Resolution Radiometer) image with the Kuroshio. Error rate criterion is used to statistically evaluate the performance of GCSED algorithm and other edge detectors for both noise free and noise contaminated images. Results and analyses show that the mesoscale features of the Kuroshio can be well identified by using GCSED method. Author (NASDA)

It is verified that the subtraction image of twice Channel 4 minus Channel 5 data of NOAA/AVHRR (Advanced Very High Resolution Radiometer) expresses the sea surface temperature pattern in the subtropical ocean well. Using this image, the next two phenomena were found. One is the existence of sharp straight edge between the northward flowing warm current and the stationary or southward flowing colder water at the sea area from about 200 km east of Batan Islands. Another phenomenon is a sea surface temperature front existing at about 23 deg N latitude line zone, and this front line coincides with the density front which was observed previously by Hakuhomaru Cruise in 1974 and also by Takuyo in WESTPAC (Tropical Western Pacific Ocean). INFORMATION CAPABILITY OF NOAA-AVHRR DATA FOR MONITORING OCEANOGRAPHIC AND ATMOSPHERIC POLLUTION **c45**

Hans-Joachim Lotz-Iwen, Stefan Werner Dech, Ruediger Glaser (Wuerzburg Univ., Germany.), and Andrea Holz (Mainz Univ., Germany.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 790-795 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The potential of NOAA-AVHRR (Advanced Very High Resolution Radiometer) data for monitoring large-scale pollution phenomena is demonstrated by means of two case studies. The first study focuses on the polluting effects of smoke plumes from burning oilfields in Kuwait as a consequence of the Gulf War. Beyond the analysis of spatial distribution, height thickness, and dynamic aspects of the smoke plumes, the effects of fallout in the southern Mesopotamian region have been investigated. During and after the Gulf War, DLR's (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt) DFD (German Remote Sensing Data Center) acquired NOAA-11 passes over the Gulf region showing smoke plume phenomena and surface contamination effects both in desert and vegetated areas. Qualitative information with respect to spatial distribution, height, thickness, and dynamic aspects of the smoke plumes were derived. In addition, processing of satellite imagery from April, May, and June confirmed that large vegetated areas in the Mesopotamian region have been obviously affected by fallout. As this region belongs to the most important agricultural areas in Iraq, a fundamental lack of food supply must be expected. Sea surface contamination in the Black Sea has been detected and monitored during late summer 1990 by evaluating multispectral data from NOAA-AVHRR. Analysis of sea surface temperature and surface currents results in conclusions with respect to sediment transport from the Danube as well as to algae plumes growth forced by nutrient supply and suitable climatic conditions. SATELLITE OBSERVATIONS OF THE NORTHEAST MONSOON COASTAL CURRENT **c43**

S. S. C. Shenoi, A. D. Gouveia, S. R. Shetye, and L. V. G. Rao *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 796-801 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Satellite infrared observations from the Advanced Very High Resolution Radiometer (AVHRR), during November 1987 to February 1988 and hydrographic data from the eastern Arabian Sea are used to describe the poleward flowing coastal current in the eastern Arabian Sea during the northeast monsoon. The current, identified by a band of warm water, forms in November in the south, and is best developed during December to January when it can be traced along the entire coast of the eastern Arabian Sea. Off the southwest coast of India (10 deg N), the current was approximately 400 km wide. At about 22 deg N, the flow was restricted mainly to the vicinity of the continental slope and the current was a narrow jet of about 150 km width. Further north the core of the current narrowed down to about 50 km and turned west following the shelf off Pakistan. The current carried warmer waters (greater than 29 C) of southern origin to the north Arabian Sea. In the northern half of the coastline (north of 15 deg N), the temperature within the core of the current was about 1 C above the ambient temperatures. Author (NASDA)

ASPECTS OF APPLYING A RELAXATION METHOD TO COMPUTING SEA SURFACE VELOCITIES FROM SEA SURFACE TEMPERATURE IMAGES **c48**

Q. X. Wu, D. Pairman, and E. J. Barnes *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 802-807 Sponsored by New Zealand Foundation for Research, Science and Technology, New Zealand (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

There has been increasing interest in computing sea surface advective velocities from sequential satellite thermal infrared images in recent years. Computational methods include those based either on Maximum Cross Correlation (MCC) or on inversion models, and the recently developed iterative approach termed the relaxation technique. Two aspects of the relaxation technique are discussed in this paper with regards to its practical implementation. One of them is concerned with employing different numbers of thermal feature points, and the other is related to the use of the Discrete Compatibility Functions (DCF) and the Continuous Compatibility Functions (CCF). It is shown that using a large number of feature points gives better results but at a cost of increased computation time. Similarly, CCF is advantageous in performance but not in speed compared to DCF. A major limitation of the relaxation method is its weakness in the treatment of strong shearing motion. The current research strategy towards overcoming the limitation is outlined. Author (NASDA)

SEA SURFACE TEMPERATURE DIFFERENCE BETWEEN NOAA/AVHRR AND IN-SITU OBSERVATION c48
Hiroshi Ichikawa, Katsutoshi Nishimura, and Masaaki Chaen *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 808-813 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

In order to elucidate the origin of the large difference between sea surface skin temperature (Temp/Sat) estimated by MCSST (Multi-Channel Sea Surface Temperature) technique and the subsurface in-situ bulk water temperature (Temp/in-situ), the vertical gradients of water temperature near the sea surface were measured by a CTD (conductivity, temperature, and depth) meter lowerings at 18 stations across the Kuroshio in the Tokara Strait south of Japan in December 1989. The Temp/Sat were estimated by MCSST technique utilizing brightness temperature of Channel 3 and 4 of AVHRR (Advanced Very High Resolution Radiometer) on NOAA-10 together with the 18 Temp/in-situ measured at ship bottom of 5 m depth. It is found that the standard deviation of Temp/Sat from Temp/in-situ is reduced about one half by correction using the in-situ vertical gradient of temperature. The corrected temperature difference is well correlated with the heat flux from the ocean. Author (NASDA)

APPLICATION OF NOAA AVHRR DATA TO FISHERIES c43
Hideo Tameishi, Shin Fujita, and Katsuya Saitou *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 814-819 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Presently, JAFIC (Japan Fisheries Information Service Center) makes the satellite aided oceanographic condition charts with NOAA AVHRR (Advanced Very High Resolution Radiometer) data and sends these charts to fishing boats in ocean. It was shown that the NOAA AVHRR data were applicable to fishing ground forecasting, and with the use of NOAA AVHRR data or imagery, a fishing and oceanographic condition chart with fishing information about current, front, intrusion of warm or cold water, and eddies can be produced by using JAFIC image processing system. It turns out that the expert system was useful and effective for extraction of ocean conditions from sea surface temperature data. Now, according to the communication between JAFIC and fishing boats operated offshore of east Hokkaido, Japan, it is shown that fishing grounds of saury, skipjack, squid, and sardine are highly correlated with the above mentioned environment. Two types of mesoscale eddies are observed using NOAA AVHRR (Advanced Very High Resolution Radiometer) infrared images. The eddy propagates along the Kuroshio front at a speed about 30 miles per day. It makes it difficult to trace mesoscale eddies with only intermittently taken images. This propagation speed is several times faster than that of the small Kuroshio meander. Author (NASDA)

INTRUSION OF KUROSHIO WARM WATER INTO SAGAMI BAY c48
Hyo Sang Choo, Takashige Sugimoto (Tokyo Univ., Japan.), and Hideo Tameishi (Japan Fisheries Information Service Center, Tokyo.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 824-828 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Warm water intrusions from Kuroshio into coastal waters are investigated focusing on Sagami Bay. Satellite AVHRR (Advanced Very High Resolution Radiometer) thermal images were used, combined with hydrographic observations and moored current meters. The results indicate that not only the branched current of the Kuroshio from the western channel but also warm streamers or intermittent intrusions of the warm water from ridges of the meandered Kuroshio front through the eastern channel are essentially important in the formation of the cyclonic circulation in Sagami Bay. Two years (October 1989 to September 1991) of NOAA AVHRR (Advanced Very High Resolution Radiometer) imageries were derived to analyze the surface dynamics in the waters off northeastern Taiwan. The observed area is 285 km by 356 km with the center point at 26 deg N, 123 deg E. The location and type of Kuroshio front was distinctly different in different seasons. The greatest extending of the front appeared in winter and had about a 4 C/100 km gradient, while the least was in summer with about a 2 C/100 km gradient. In May, October, and November, the Kuroshio anticurrent which formed an anticlockwise front was prevalent and had a life span of two to seven days. The location and feature of eddies also varied in different seasons. It was located near Taiwan in winter, moved away from Taiwan, and extended northeastward in summer. In autumn, the eddy was easily influenced by the Kuroshio anticurrent. Its life span was about 10 to 16 days. Author (NASDA)

The sea surface thermal patterns of Kuroshio around the Shirahama Oceanographic Observatory were derived using a real time imagery of NOAA APT (Automatic Picture Transmission) system. Variations of the thermal pattern indicate variations of Kuroshio as those that have been surveyed and studied intensively in relation to weather prediction, ocean prediction, or storm floods. Interrelations of Kuroshio variations and storm floods around the tower have been studied. A simple notice about a trigger of the Kuroshio variations are given. Storms may effect the minor variations on the sea surface. Some of the episodic examples could be introduced with a descriptive notice in the scope of geophysical hydrodynamics. Author (NASDA)

ADCP EVIDENCE FOR UPPER LAYER CIRCULATION IN NORTHEAST OF THE SOUTH CHINA SEA c48
Shuzhen Pu, Huiling Yu, and Songnian Jiang (National Marine Date and Information, Tianjin, China.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 841-845 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Branching of the Kuroshio into Bashi Channel or the warm current in Taiwan Strait are associated with the top layer circulation in the northeast of the South China Sea. This paper goes over the previous research results, and then uses the ADCP (Acoustic Doppler Current Profiler) observations to discuss the top layer circulation in Bashi Channel and the northeast of the South China Sea. As it is indicated from the ADCP measurements: (1) Kuroshio indeed branches into the northeast of the South China Sea through Bashi Channel. The branch of Kuroshio flows northwestward as it is measured many times, and the width and strength of the Kuroshio branch varies in time; (2) the branch of Kuroshio getting into the South China Sea might bifurcate again into the northward current off the west coast of Taiwan and the westward current in the northwest of the South China Sea; (3) the strength of the westward current in the northeast of South China Sea varies in time; (4) there is some structure like an eddy to the south of the westward current in the northeast of the South China Sea; and (5) there might be an eastward current or a northward current to the onshore side of the westward current. The results of frontal zones research in the Pacific, based on the combined analysis of ship-borne and satellite data, are presented. Both large scale oceanic frontal zones and mesoscale fronts in marginal seas have been investigated. The main types of frontal zones thermal structure have been distinguished, and comparative characteristics of frontal zones are discussed. Author (NASDA)

The commercial swordfish fishery started in Chile in 1983, but the waters off the coast of Coquimbo have not been fished on account of the colder superficial waters (13 C), as a result of the intensive upwelling that occur in this area. Analyzing the satellite temperature images of NOAA-H from 1985 to 1989 and the sea surface color images of NIMBUS-7 during 1980 to 1991, it was determined that beside the upwelling there is an oceanic plume of 15 C water, with low phytoplankton biomass (0.5 mg/cu m of chlorophyll-a) that approaches the coast. This environmental condition would theoretically allow the presence of the swordfish in the zone of Coquimbo. This hypothesis was presented to Santa Lucia fishery, which sent the F/V (Fishing Vessel) Vamas 2 for a survey during August 1989, when the fishing season for this species had finished in Chile, to test it. Nineteen swordfish were caught in three days, proving that this oceanographic structure produces the concentration of this fish. With these preliminary studies, fishing was planned in the waters off Coquimbo during 1990, and the results of those activities are presented. Author (NASDA)

The Simpson-Hunter criterion predicts the occurrence of strong tidal mixing off the midwest coast and around the southwestern tip of the Korean Peninsula. Surface coastal water in the two areas during the summer is colder than the surrounding water. The boundary between coastal mixed and offshore stratified regions is clearly marked by a thermal front on NOAA infrared imagery. Strong tidal stirring causes high concentration of suspended matter throughout the year in the study area, which is evident on LANDSAT visible images. The turbidity front formed around the southwestern corner of Korea generally is concordant with the thermal front in summer. Author (NASDA)

The accuracy of the sea surface temperature estimated by a split-window function was validated by the total data set with 390 match-ups, which were composed of the brightness temperatures by NOAA-9/AVHRR (Advanced Very High Resolution Radiometer) and the sea surface temperature by fixed buoys in Mutsu Bay. The temporal and spatial coincidence in each match-up is within 30 minutes and one pixel resolution. The standard deviation of residues by the regression analysis was 0.59 C. By referring to the meteorological data, several match-ups having large residue were found. Those were estimated to be caused by the air-sea interaction effects. By removing the match-ups with larger errors, a selected data set with 328 match-ups was prepared and the SST (Sea Surface Temperature) estimation function was recalculated. The standard deviation of residues reduced to 0.34 C. Author (NASDA)

Measurements of surface velocity, sea surface temperature, and sea-level barometric pressure on ocean basin space scales and seasonal time scales are required in the World Climate Research Program. The scientific rationale is to obtain a global description of the mean state of these variables, to map their variability, and with this data to study processes of momentum and heat transport in the upper ocean and improve ocean circulation models. A global Surface Velocity Program (SVP) has been organized in thirteen countries to obtain these measurements from low cost ARGOS tracked Lagrangian drifters, 350 of which are now deployed in the Pacific and Atlantic Oceans. SST (Sea Surface Temperature) and barometer data from drifters are used by operational agencies in real time for improving weather forecasts and modeling and predicting short term climate change. A global population of 900-1,000 drifters will be needed by 1997 in support of the Global Climate Observing System (GCOS). Since 1985, Scripps Institution of Oceanography (SIO) has been a center for drifter technology development and deployments. This is a report of the technical and scientific progress in SVP and ACCP (Atlantic Climate Change Program) organized in support of the WOCE (World Ocean Circulation Experiment)/TOGA (Tropical Ocean and Global Atmosphere Program) in the U.S. since 1988. A prototype of a shuttle type Autonomous Underwater Vehicle (AUV), which is named 'ALBAC', was designed and constructed for oceanographic measurement of the water column from the surface to the seabed. The ALBAC mainly consists of a cylindrical body and a pair of wings that provide lift force to let the vehicle glide horizontally without consuming energy from batteries. Therefore, the mother ship is not obliged to be shifted above the measuring point for it's deploy. The constructed ALBAC (1.4 m in length, and 45 kgf in dry weight) is able to glide 20 degrees down from horizontal plane and dive to the depth of 300 m. To make the total system reliable, major equipments except some ultrasonic apparatuses are installed in one pressure chamber. For scientific measurement devices, 3 liter payload space is available in this chamber. The attitude of the vehicle in gliding is controlled automatically using two balance actuators that displace the center of gravity longitudinally and laterally.

Many of the large construction projects currently in progress in Japan are under water. The actual sites, however, vary greatly in terms of water depth, geology, wave action, tidal currents, and other characteristics. For example, in the cases of the Trans-Tokyo Bay Highway and Kansai International Airport, large artificial islands have been constructed on an extremely soft seabed where the water depth is in excess of 20 m. In the case of the Honshu-Shikoku Bridges project, the world's largest suspension bridge is presently being constructed over water 50 m deep in an area where tidal currents reach 8 knots. To carry out construction work under such complex marine conditions, it is extremely important that prudent surveys and planning is implemented in advance and that adequate construction management is performed. The system described in this paper allows marine information to be collected over a wide area in a continuous and quick vessel-based process using ultrasonics. It has already been applied to many phases of the construction procedure ranging from surveys to construction management, and the more than 20 projects which have made use of the system so far include the large projects described above.

A buoy system for monitoring marine weather and marine life abundance at the Yamato Bank in the Sea of Japan has been developed. The system observes marine weather parameters and acoustic echo under the buoy every three hours. The data is transmitted in real time to the receiving center of the Japan Meteorological Agency via the GMS (Geostationary Meteorological Satellite). The buoy was moored at a site with a depth of 305 m on 9 March, 1990, and the observation was carried out until the end of March 1991. The data obtained of wave height and wave direction were reasonably accurate. An installed echo sounder recorded some typical changes of marine life abundance. The buoy system has been practically completed.

An image-processing system available at the Center EULA for Environmental Studies, University of Concepcion, and the microcomputer software packages RESOURCE and DRAGON to display and manipulate images, were used to process LANDSAT TM (Thematic Mapper) and SPOT images covering the Gulf of Arauco, Bay of San Vicente, Bay of Concepcion and adjacent areas in central Chile, all largely affected by environmental constraints, the impact of population growth and multiple industrial development. Individual bands or their combination were used to localize and measure the extension of the effect of pollution due to suspended particles, and/or thermal inputs along the coast, with a resolution of 30 by 30 m for Band 1 to 5 and 7 and of 120 by 120 m for Band 6 (thermal). Panchromatic SPOT images and aerial orthophotographs taken with a ROLLEY metric camera also permitted the study of the dispersion of particulate-suspended material and sediment in estuarine areas with less than 10 by 10 m resolution. The general dynamics of coastal oceanographic processes in the area of study is discussed regarding local upwelling events, the effects of rivers, sedimentation pattern and, local estuarine input into coastal areas. The identification and degree of comparative pollution is correlated with areas of concentrated industrial or urban effluents, corroborating in-situ measurements and observations. Author (NASDA)

In recent years, artificial shore protection works and embankments, which are concrete structures, have been increased as a result of active water front development, and natural sea shores have almost disappeared. The organisms living in the sea are disturbed, so the water front development that includes the protective and landscape function is desired to increase the existence of organisms living in the sea. The experiments were made using porous concrete that has large contact area with sea water. The experiments were made with piled concrete aggregates under sea surface and the relationship between the number of species and amount of organism and changes of water quality were examined. As a result, the number of species and amount of organisms were found to depend on the size of aggregate, and the transmissivity was improved by using porous concrete aggregate compared with natural stone. ROLE OF REMOTE SENSING AND ITS COST EFFECTIVENESS IN SITE SELECTION FOR COASTAL AQUACULTURE **c43**

R. Sudarshana and M. S. Siddiqui *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 904-909 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Coastal aquaculture in brackish water expanses of the tropical zone has gained importance as a means of supplementing food production for the ever increasing demands of multiplying populations. Nevertheless, the process is very slow due to lack of inventory of aquaculturable areas in the coast, and there are not many reliable field methods that can produce comprehensive surveys. In view of this, some experiments were made in India to delineate aquaculturable areas using the indigenous data of Indian remote sensing satellite. Termed as the Weighted Index Scheme (WIS), the approach was developed on the incidence of natural processes in determining the potentiality of estuarine brackish water areas. Initially, three estuaries on the west coast were critically analyzed using WIS. Further, the whole of about 6,400 km of Indian coast line was considered and in the background of available statistics on yield, turn over, and profits, projections for the whole coastline in terms of production and yield were made. The cost of remote sensing efforts has also been calculated and it has been demonstrated that the use of remote sensing techniques would only amount to about 0.4 percent of the profits that are obtainable from country-wide exercise. A balance sheet of expenditure and profits in using modern techniques is presented, and the paper upholds that remote sensing can substantially enhance the food production and earnings from coastal aquaculture. The aim of this study is to discuss the seasonal variability of surface ocean color in the Omura Bay, Nagasaki Prefecture, Japan, using multitemporal LANDSAT-5 TM (Thematic Mapper) data. For this purpose, thirteen sets of sea-truth data collected near-simultaneously with LANDSAT-5 TM overpass, consisting of five data sets in autumn, three data sets in winter, three data sets in spring, and two data sets in summer were used to develop the seasonal estimation models using simple linear regression. Among the algorithms, the ratio of atmospheric corrected Digital Count (DC) TM-2 to TM-1 (TM-2/TM-1) consistently correlated best with chlorophyll-a for each season. Weak correlation was found for total pigments, and no correlation for Total Suspended Solid (TSS). Based on this result, it could be concluded that the water of the Omura Bay is optically dominated by living phytoplankton. Validation of the models yielded the Root Mean Square (rms) error of 1.5, 1.0, 0.8 and 0.5 microgram/l within the chlorophyll-a ranges of 1 to 8, 1 to 9, 1 to 8, and 0 to 4 microgram/l for autumn, winter, spring, and summer, respectively. The around-the-world cruise of R/V (Research Vessel) Hakuho-maru was performed by Ocean Research Institute, University of Tokyo during 130 days. Acoustic measurements at four frequencies with small organisms sampling were carried out 43 times at 19 stations. The biomass represented by settling volume was compared with acoustic volume scattering strength (SV in decibels) at each frequency. The relationship between biomass (transformed into logarithm) and SV was obtained as linear regression equations. Slopes of the regression equations for four frequencies were all close to one. There was a decreasing tendency of SV with increasing frequency. This result suggests that resonance phenomenon occurs in scattering process of the small organisms. Author (NASDA)

PROPERTIES OF SPECTRAL REFLECTANCE OF CROWN AND CROWN STRUCTURE OF MANGROVE SPECIES IN OKINAWA c43

Kazuhiro Satou, Dwi Setyono, Osmar DeMoraes (Empresa Brasileira de Pesquisa Agropecuaria, Santa Catarina.), and Takashi Hoshi (Ibaraki Univ., Hitachi, Japan.) *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 922-927 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The fundamental data of this study is spectral reflectance measurements above the crown layer of a mangrove stand with three mixed species. Several indexes related with the shape of spectral reflectance curve, and several combinations among these indexes were examined to separate mangrove species. Comparatively good results were found out as combinations of a ratio of reflectance at 850 nm divided by reflectance at 650 nm, and two gradients calculated from reflectances at 850 nm and 650 nm or 550 nm. It was considered that spectral reflectance properties of the mangrove crown related closely with the structure of crown. Author (NASDA)

APPLICATION OF REMOTE SENSING FOR COASTAL MANAGEMENT IN THE NORTH COAST OF JAVA c43

A. Hartoko and D. Suprapto *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 928-935 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The study is intended to explore possibilities of applications and uses of remote sensing/satellite data for coastal management program holistically. The study itself is a part of a five year research program. The purpose of first year study is to map and monitor the growth of a mangrove area, a brackish water pond area, and the seasonal pattern of sedimentation, sea surface temperature, and primary productivity. The approach used LANDSAT satellite data, MSS (Multi Spectral Scanner) channel 4, 5, 6, and 7. The means was a principal component transformation of channel 1, 2, 3, and 4. The software used is a CCRS (Canadian Center for Remote Sensing) computer package. The sea surface temperature was derived from NOAA/AVHRR (Advanced Very High Resolution Radiometer) satellite data. Sampling for the sea truth data for suspended solids (mg/lit), primary productivity (chlorophyll content, mg/cu m), and sea surface temperature have been done simultaneously in 1991. The first year study program revealed a significant increase of suspended solid during the west monsoon (November-February) due to the pattern of the predominant wind direction. Sea surface temperature in dry monsoon ranged from 22.5 to 30 C, and from 22.5 to 28 C in wet monsoon. The study on the image on mangrove area of Cilacap Bay revealed that mangrove coverage in 1986 was denser than the following year. Author (NASDA)

A sand spit had been developed on the coast of the volcanic island of Iwo Jima (sulfur island). The distribution of median size of this spit's sand and an air photograph are used in order to make clear the growing processes of this spit. The distribution curves of median size show the predominant maximum and minimum looks periodically, and many remarkable wavy patterns are visible in an air photograph. If such two distribution curves will be laid on, the frequency domain of these two curves can be found to coincide well with each other. The fact that these wavy patterns are overlapped so well, enables the prediction of the growing processes of this spit more clearly. Author (NASDA)

The land cover classification in Kitami which covers an area of 12 by 9.5 km is done after geometric correction, and the monthly mean albedo is estimated for seven land cover categories. The monthly mean of Kitami's areal evapotranspiration (ET) is obtained by Kojima's equation in winter and by Morton's equation in other seasons. The annual change in estimated ET which reach its maximum value in July correlates reasonably well with ET in an observation field. The influence of both slope solar radiation and housing land development on ET are examined. Author (NASDA)

An area of 2,125 sq km located in the northwestern part of the Iranian Central Plateau, which is a sub-basin of Iranian internal watershed, was selected for this investigation. The main objectives of this investigation are: (1) construction of a land use map and land cover map; and (2) measurment of the area coverage in all units. On the basis of LANDSAT imagery and available data which were interpreted, the final map was prepared at scale of 1:1,000,000. In the land use map, several major units such as agricultural lands, forest lands, range lands, wet lands, barren lands, water resources, and urban areas have been recognized. Results obtained in this investigation indicate LANDSAT imagery could be used for land use and land cover mapping in an area and undoubtedly could be considered as an essential tool for this type of investigation in the country. The use of reference data in statistical algorithms is the standard pattern recognition technique in satellite remote sensing, although it is costly. This paper presents a method that minimizes the quantity and quality of reference data in classifying spectral data into land cover classes. With this method, the reference data is limited to land cover maps, which could be easily obtainable for any geographical location. The method uses cluster analysis and factor analysis for classification. The spectral classes or the natural grouping in a satellite image is identified by clustering. Factor analysis is carried out with these spectral classes, and physical properties of the factors are interpreted on factor loadings. Using factor interpretation, land cover classes of these spectral classes are estimated. Typical spectral response patterns of land cover and band ratios are used as supporting data in spectral classes interpretation. Samples that belonged to each estimated land cover class are used as the true reference data of the particular class and the whole scene is classified using a maximum likelihood algorithm. Application of the above method was attempted in two different cases such as mapping severity of forest fire damage, and estimating the land cover classes, using LANDSAT Thematic Mapper (TM) data. It was found that the accuracy of severity of fire damage mapping was 78 percent and land cover mapping was 80 percent, when compared with aerial photographs. Author (NASDA)

During the two WOCE (World Ocean Circulation Experiment) PR21 cruises and the Joint Sino-Philippino cruises, hydrographic surveys were made around the northern part of Luzon Island. Both CTD (conductivity, temperature, and depth) and chemical water samples were taken for studying the coastal hydrography and Kuroshio near Luzon. In the region northeast of Luzon, both the geostrophic calculation and the Acoustic Doppler Current Profiler (ADCP) data suggest that the Kuroshio transport in June 1991 contributes only part of the Kuroshio transport further downstream near southeast of Taiwan, where a significant portion of Kuroshio water comes from the westward current between 18 deg N - 22 deg N. In the region west of Luzon, the on-shore current splits at 15 deg N. It forms northward coastal current (against the NE (Northeast) winter monsoon) north of 15 deg N, and southward coastal current south of 15 deg N where monsoonal wind is relatively weaker than the northern region. To balance the fresh water and salt, a counter clockwise gyre in the South China Sea north of 15 deg N is suggested. Author (NASDA)

A buoy-mounted Acoustic Doppler Current Profiler (ADCP) was deployed on the shelf-break off the northeast coast of Taiwan to monitor current variation in the upper ocean. The acquired data was used to study the variations of low-frequency current and semidiurnal tidal current. The low-frequency flow in the upper water column was initially southwest and then abruptly turned northwest. This abrupt change occurred in mid-October, starting from the surface layer and then gradually extending to the deeper layer. In contrast with this flow, the low-frequency flow in the lower water column was over the entire record. The abrupt change of current from southwest to northwest is related to the intrusion of Kuroshio. Examination of the wind record at Pengchiayu showed that the local wind and current were incoherent. The intrusion of Kuroshio appears to be induced by remote factors. Both barotropic and first baroclinic tides were found to be important in this area. The intrusion of Kuroshio had relative small impact on the barotropic tide but large impact on the baroclinic tide. The speed of barotropic and baroclinic tides were comparable before the intrusion. After the Kuroshio intruded, the baroclinic tidal speed was enlarged. The intrusion also changed the orientation and the ratio of two axes of ellipse for both barotropic and baroclinic tides, but the later one has more significant change. The change of local water stratification and background low-frequency current may be responsible for the variation of the semidiurnal tide. Author (NASDA)

SEDIMENTATION RATES AND PARTICULATE FLUXES IN THE SLOPE AND DEEP SEA AREAS OFF EASTERN TAIWAN **c48**

G. W. Hung and Y. Chung *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 975-981 (For primary document see N94-12635 01-42)

Th-230 and Pb-210 were measured for sedimentation rate and flux determinations from several cores collected from the East China Sea continental slope and the deep-sea areas off eastern Taiwan. In the East China Sea slope area, the sedimentation rate as determined by the Pb-210 method was 0.28 cm/year for the past 100 years. In the deep sea areas off eastern Taiwan, the rates as determined by the Th-230 method from two cores were similar at about 2 to 3 cm/k year. Another core was located to the southeast of Taiwan, the rate was 0.6 cm/k year. These results suggest that the river input and runoff from the east coast of Taiwan have contributed a significant amount of sediments into the deep sea off the east coast. The sedimentation rate obtained in the East China Sea Continental Slope is about 100 times greater than that in the deep sea off the east coast, suggesting that additional major source from mainland China may be responsible for such high sedimentation rate. There are indications that the output of sediments from both the Yangtze and Yellow Rivers may be transported southward by coastal current before deviating eastward to the north of Taiwan. Sediment traps deployed repeatedly near the coring site in the East China Sea yield an apparent particulate flux of about 2.5 gm(sup -2)d(sup -1). The flux is at least five times as great as the above value. As the current speed is quite high in the area, the trapping efficiency may have been significantly reduced. Author (NASDA)

Air-sea interaction in the OMLET (Ocean Mixed Layer Experiment) area has been studied to understand mechanisms of variation of a layer in the vicinity of the ocean surface, which covers a wide area and has a time scale on the order of a day. Remote sensing data of several satellite sensors are employed for estimation of the air-sea fluxes together with in-situ observations of the OMLET. The OMLET region is investigated during April to May, 1988, when the OMLET cruise KH88-2 was performed. Author (NASDA)

Using Sea Surface Temperature (SST) images derived from Advanced Very High Resolution Radiometer (AVHRR) data, a number of meso-scale ocean phenomena such as fronts, eddies, and upwellings have been investigated in the China Seas. Firstly, five kinds of temperature fronts have been observed and their generating causes have been studied, they are shelf-break front, tidal mixing front, estuarine discharge front, coastal upwelling front, and a front formed in the junction of two currents with different natures. A general map indicating the locations and types of eight main frontal zones in the eastern China Seas has been presented. Secondly, several meso-scale eddies have been found, their causes and evolution processes have been examined, among which a cyclonic cold eddy with a lifetime of nearly one month in the northern Yellow Sea is reported and analyzed for the first time. In-situ measurements of some of the eddies have shown good agreement with satellite observations. Thirdly, behavior of the famous Zhejiang coastal upwelling has been identified and studied. Satellite infrared images enable us to recognize ocean phenomena such as current, eddy, front, and others as macroscopic patterns. However, the recognition has still remained ambiguous in minute parts. A theoretical method to extract warm eddies from NOAA/AVHRR (Advanced Very High Resolution Radiometer) images is investigated. Based on an assumption that the shape of an eddy is approximately ellipse, the detections of the size, location, and orientation of an eddy were examined by using a generalized Hough transformation. As a result, ellipses in various types were detected from images. One of them could be along an eddy and the other overlaid on fronts close to an eddy. As a warm eddy possibly causes a cold streamer as well as fronts, the detection of ellipses overlapped on an eddy and front leads to a prediction of a cold streamer. Author (NASDA)

In recent years, large power stations have been constructed close to each other on the coast of Japan. The need of monitoring more widely and immediately the sea adjacent to power stations has been increasing. The satellites observation has been applied as an effective method for this purpose. The objective of this study is to estimate the applicability of the satellite data for the monitoring of coastal environments. First, the applicability of the LANDSAT/TM (Thematic Mapper) data for the monitoring of warm water discharged from power stations was examined. The distribution of the Sea Surface Temperature (SST) was estimated by the regression analysis with the field data measured with the thermometer. The measuring ratio of the available LANDSAT/TM data for the monitoring was evaluated at 57 power stations in 1987 and 1988. Second, the template method, which computes the velocity of surface water mass displacement using the temporal change of the SST distribution estimated by the NOAA/AVHRR (Advanced Very High Resolution Radiometer) data, was applied to three oceanic areas in Japan. The controversial points in applying the template method are discussed. Author (NASDA)

Time series satellite infrared observations of NOAA-11 AVHRR (Advanced Very High Resolution Radiometer) were carried out around the Yamato Rise in the Japan Sea from October 1990 to January 1991. In the same period, a ocean buoy system moored over the Yamato Rise has been gathering sea surface temperature and other marine meteorological parameters. Buoy observation is useful to grasp the movement of a polar front in the Japan Sea. On the other hand, satellite observation is applied to understand spatial variabilities of the polar frontal system. As a result, movement of the polar front is connected to variabilities of SST (Sea Surface Temperature) observed by the moored buoy. A warm eddy existing on the western side of the Yamato Rise is an important phenomenon in understanding the variabilities of the polar frontal system over the Yamato Rise. Author (NASDA)

Historically, sea surface temperatures were measured from bucket samples or engine cooling water samples that measure the temperature of the upper meter of the ocean. Known as the bulk sea surface temperature, this measurement has been used to compute air-sea heat fluxes using empirical formulae. Infrared satellite sensors collect radiation emitted from the millimeter thin skin of the ocean. Depending on atmospheric and oceanic conditions, this skin temperature differs from the bulk temperature on average by about 0.5 C. Maximum bulk-skin differences can be as large as 1.4 or -1.2 C. Measurements of the skin temperature from ship-mounted radiometers are used with coincident measurements of bulk temperature to study these differences and their correlations in time and space. A one-dimensional numerical model is used to simulate both skin and bulk temperatures as a function of surface heat fluxes and wind stress. Author (NASDA)

A sharp front is found at the northern edge of the warmest area along the Kuroshio in each thermal image (hereafter, the 'surface Kuroshio front'). The relationship between the Kuroshio axis and the surface Kuroshio front was analyzed. It was found that the surface Kuroshio front always coincides with the Kuroshio axis in the area of the Pacific Ocean, east of Japan, whereas it tends to coincide with the northern edge of the strong flow of the Kuroshio in the East China Sea and the area of the Pacific Ocean near Japan. In other words, the relationship depends on the area. Therefore, it was ensured that the surface Kuroshio front is a good measure of the location of the Kuroshio axis. Then, the location of the surface Kuroshio front was analyzed statistically to examine the variability of the Kuroshio. The transition of the type of the Kuroshio meander in August 1990 was successfully identified. It was also found that the standard deviation of the variation in the location of the surface Kuroshio front is the smallest (less than 20 km) in the regions off Shikoku Island and Boso Peninsula, Japan; therefore, the Kuroshio path is the most stable here. A three-dimensional (3-D) semi-analytical mixed layer remote sensing model which includes the horizontal advection and diffusion processes in previous one-dimensional (1-D) model have been recently developed. The 3-D model can be used as a supplement to the 1-D model in the area where advection is important and for a finer resolution grid prediction. The 3-D thermal inertia model is based on the 3-D thermal energy conservation equation. Using sine transformation and inverse sine transformation methods, the solution for mixed layer thermal inertia which, in turn, can be used to calculate mixed layer depth using a similar method, was obtained. In the solution, the thermal inertia, which is proportional to the mixed layer depth, is expressed as functions of Sea Surface Temperature (SST) changes (delta SST), heat flux (Q), and surface layer velocity (u and v). The vertical entrainment and wind effects are accounted for in the model by changes of delta SST, e.g., if vertical entrainment is larger, delta SST will be smaller and vice versa. The model was tested using the data from AVHRR (Advanced Very High Resolution Radiometer)-MCSST (Multi-Channel SST) data set and COADS (Comprehensive Ocean Atmosphere Data Set) for the North Pacific Ocean. The model predicted mixed layer depths compared favorably with the mixed layer depths calculated from fourteen years of VOS (Vehicle on Stand)-XBT (Expandable Bathy Thermograph) observation data. The model/data comparison also exhibited a number of mesoscale features of seasonal changes and anomalies of the mixed layer depth. Author (NASDA)

The adjoint method is an elegant data assimilation technique to find the solution to the numerical model equations best reproducing all available physical observations wherever located in space and time. The desired numerical model solution is the one which minimizes the cost function defining the extent to which the model results fail to reproduce the data. In searching for the minimum of the cost, the variables of the model cannot be adjusted independently because they are related by the model equations. These constraints are incorporated into the optimization problem via a Lagrange function that has a saddle point which corresponds to the constrained minimum of the cost. The GFDL (Geophysical Fluid Dynamics Laboratory)-GCM (General Ocean Circulation Model), a nonlinear, primitive equation model that has excellent numerical conservation properties, was used to build a model fitting procedure to assimilate the Eastern Mediterranean climatological data. Seasonal steady state general circulation induced by T (temperature), S (salinity), and wind data are already assimilated and used to start the time dependent data assimilation of Sea Surface Temperature (SST) from AVHRR (Advanced Very High Resolution Radiometer) imagery. Application of near infrared data for monitoring of a benthic diatom in a tidal area was examined in Ariake Sea, western Kyushu. CCT (computer compatible tape) count on the dense area was apparently different from that on the other area and indicated about half the value of paddy fields. Images taken by the spectral slice method using the near infrared band was effective in monitoring the high density area of a benthic diatom. For detection of the dense area, it is necessary to be at a lower tidal level. However, the dense area occupied a small portion of the tidal area at low tide. The dense area was found in the west coast and never found in the east coast of the Ariake Sea. As this tendency of distribution of dense area well coincided to that of bivalve production, the detected area in this procedure should indicate potential productivity in the tidal area. Using sequential AVHRR (Advanced Very High Resolution Radiometer) images in November 1983, near-surface advective velocities in the region Kuroshio south of Japan are derived. For deriving the velocities two methods are used. One is the Method of Cross Correlation (MCC), using image pair, and the other is geostrophic approximation, using single image. Both of the velocity vectors are found to be comparable in magnitude and direction. While the approximated geostrophic velocities exhibit the Kuroshio large meander, the MCC velocities failed to derive any velocity vectors associated with the large meander. The vector fields off Kii Peninsula demonstrated an onshore intrusion of Kuroshio water. Near the Bungo Sidan channel, the MCC velocities appeared to be the geostrophic surface currents perturbed by south easterly winds. Author (NASDA)

POLARISATION OF BACKSCATTERING RADIATION AT REMOTE SENSING OF OCEAN WITH IMPULSE LASER BEAM **c36**
Alexander P. Vasilkov, Timothy V. Kondranin, and Yegeny V. Myasnikov *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1058-1062 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The problem determining polarized backscattering radiation in a highly anisotropic scattering medium illuminated by impulse laser beam is solved. The expressions for the Stokes vector of the backscattering radiation are obtained in a small angle approximation of the vector radiative transfer equation. The influence of the optical properties of the water and remote sensing geometry on the temporal dependence of the degree of polarization is investigated. The obtained solution also allowed for the analysis of the effect of optical property stratification on the time dependence of linear polarization of backscattering. A method for the determination of the light scattering coefficient vertical distribution from the measurement of the linear polarization time dependence of the backscattering radiation is proposed. The experimental verification of this method is reported. Author (NASDA)

Analysis of satellite visible band and infrared images of the northwest Pacific Ocean reveals typical mesoscale elements of nonstationary dynamics (vortices, jets, and their combinations) and areas of their intensive generation. The main processes, which condition is a nonstationary dynamics in the region such as velocity shear of different kinds, regulating of various non-organized disturbances, processes in a marginal ice zone, eddy evolution, and eddy-front interaction are indicated. Interactions of eddies with the Kuroshio and Oyashio fronts are shown to condition the near-surface circulation in the subarctic frontal zone frequently at distances up to 300 km from the initial eddy. The possiblity of decoupling the near-surface dynamics with the deeper one is considered. Author (NASDA)

OPTIMUM SELECTION OF SPECTRAL CHANNELS IN THE PROBLEM OF REMOTE SENSING OF PHYTOPLANKTON CONCENTRATION IN OCEAN WATER **c51**

V. P. Kozlov, J. M. Levin, and L. V. Zolotukhin *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1073-1074 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

A new method is proposed to estimate phytoplankton (chlorophyll) concentration in ocean water at the maximum accuracy by measurements of the upwelling radiation spectra conducted by a ship or satellite. The method is based on the results of the mathematical theory of experimental design. The accuracy can be strongly increased by optimum selection of spectral channels for the measurements. A convergent iterative algorithm is proposed for searching for optimum channels and corresponding time intervals. The algorithm is realized as a routine in the PASCAL language. The input data for this algorithm are correlation characteristics of the system: spectrum of upwelling radiation to chlorophyll concentration (C). Increasing the number of both joint and separate measurements of the upwell radiation and C from a ship and satellite will make it possible to improve the accuracy of defining optimum spectral channels and consequently accuracy of the C estimate. The method of statistical simulation can also be used to determine the correlation characteristics needed for searching for optimum channels. Author (NASDA)

The report is devoted to the research into the spatial-temporal spectrum of wind waves and group characteristics of the wave disturbances related to it. The study is based on the field in-situ data. Results of the research on the variability of one-dimensional frequency spectra of waves, and functions of the directional distribution of the energy of wind waves are described. The investigations of the equilibrium range of wave spectrum and the kinematic characteristics of the groups of wind waves related to the initial wave spectrum were also reported. Author (NASDA)

The second-order closure model is used to estimate kinetic energy of turbulence, its dissipation rate, and turbulent fluxes of density in the Pacific equatorial undercurrent. Numerical solutions are presented as adaptive adjustment of turbulence parameters to corresponding profiles of density and velocity. The latter were collected during the 51st cruise of the R/V (Research Vessel) Academic Kurchatov in the central part of the undercurrent on October, 1990. Simulations showed that active turbulence is mainly concentrated above and below velocity maximum within high-shear layers. Magnitudes of dissipation rate found there approach the level of about 2 times 10(exp -3) Wm(exp -3). Comparison of the modeling results for the dissipation rate with ones obtained in direct measurements proved to be in close agreement. Author (NASDA)

THE PACIFIC SUBARCTIC FRONTAL ZONE: STRUCTURE AND DYNAMICS **c48**

T. R. Kilmatov and V. A. Kuzmin *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1095-1100 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Some new aspects of the structure and dynamics of the thermocline, halocline, and density fronts in the Subarctic Frontal Zone (SFZ) are presented. Joint analysis of the horizontal distribution of temperature, salinity, and density on meridional hydrographic routes crossing the Subarctic Front (SF) has been conducted to illustrate the peculiarities of the horizontal distribution of those parameters in the upper 500 m layer in the SF. Several correlation types can be used to determine structural boundaries, for example, of eddies and jets. The changes of the horizontal temperature-density and salinity-density relationships may be used to determine the position of the SF. The seasonal variation of the caballing process at the SF and the structure of intermediate water of lowered salinity are discussed. The experimental observation in the North Pacific confirm indirectly that the interannual periodicity of the caballing effect plays an important role at the SF. Influence of stratification on the cross-structure of the density front are mathematically described. Author (NASDA)

The method is developed to measure the rho, S, T, and P (Density, Salinity, Temperature, and Pressure) parameters in the ocean via the measurement of the only thermodynamic parameter, namely the refractive index n(S, T, P) of sea water. The method is based on the differential optical compensation of the measured refraction index in regard with any two out of three measured parameters (S, T, P). The precision measurement is made by a multichannel photoheterodyne interferometer. On the basis of this method, a set of oceanological devices, which do not have analogs in the world, was constructed: (1) a laser interference refractometer; (2) the optical nSTD (Refractive index, Salinity, Temperature and Depth)-probe without S, T, D sensors with a resolution of delta n = 3 times 10(exp -7), delta S = 1.5 times 10(exp -3) percent, delta T = 3 times 10(exp -3) C, and delta P = 0.2 dbar (delta P is independent on depth); and (3) the optical sensor for the sea surface level supplied with a thermocompensation system. It has resolution of a 2-3 mm water column. This resolution does not depend on the depth. The sensor is intended for exploration in the oceanic bottom moored stations and in the systems prediction of tsunami. Author (NASDA)

A DETAILED INVESTIGATION OF THE BENTHIC REGIME IN THE CLARION-CLIPPERTON PROVINCE OF THE PACIFIC AND A FORECAST OF CONSEQUENCES OF MANGANESE NODULE MINING **c48**

Evgeny A. Kontar, Gleb N. Baturin, and Tatiana A. Demidova *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1107-1112 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Features of bottom currents in the Clarion-Clipperton province of the Pacific should be one of the most important components defining the consequences of future mining of deep water manganese nodule deposits. The problem of bottom layer disturbance, its scales, and peculiarities due to mining, have been forecasted on the basis of the available data on benthic current activity in the region. Both published data and that obtained in experiments with pop-up self contained bottom stations were employed. As an example, features of the benthic currents circulation of one detailed area of the province which is rich in high grade nodules are discussed. This includes observed 'benthic storms'. Bottom relief, the oceanological and sedimentary situation, physical properties of the bottom sediments and nodules, the capability of benthic currents of different velocities in reworking and redepositing mining wastes, as well as different excavation schemes are taken into account in estimating future disturbance of the area. This has obvious relevance to environmental protection policies. Author (NASDA)

Circulation of bottom currents in the Pacific is presently believed to be one of the most important components defining consequences of increasing ocean pollution. Wastes of differing nature are accumulated in deep depressions in the ocean as well as, in different forms, in near bottom ocean water and in bottom sediments. Taking into account the evident importance of the problem, pop-up self-contained bottom stations designed at the Shirshov Inst. of Oceanology, Moscow, are equipped with one to five 'Potoc' current and temperature meters which are located 2 to 35 m above the sea floor, as well as several sediment traps and hydrochemical sensor modules for recording the time variation of dissolved oxygen. On the basis of experimental data obtained synchronously from three to ten of the stations deployed on the bottom for several months, the distances, directions, and paths of mass transport are calculated; the possible zones both of stagnation and of active oxygen exchange due to hydrodynamic peculiarities are mapped; and the flow of suspended particles coming down from the ocean-surface which defines contamination of the bottom are estimated. Other features of bottom currents relating to bottom pollution are discussed. Author (NASDA)

Outline of the autonomous self-contained bottom pop-up stations designed at the Shirshov Inst. of Oceanology, Russian Academy of Sciences is described. The stations are provided with an analog and digital magnetic recorder designed for continuous work during 45 days which enables storage of seismic information by six channels. For measurements, the stations are equipped with a three-component block of geophones of chemotron type which are used to measure variations of the oceanic bed within a frequency range from 0.3 to 20 Hz. The pop-up carrier of the stations has two individual instrument containers. The measuring complex also comprises a hydrophone channel and some other autonomously functioning devices; for instance, a bottom current and temperature meter, etc. Author (NASDA)

REMOTE SENSING OF LIGHT SCATTERING COEFFICIENT OF SEA WATER VERTICAL DISTRIBUTION BY THE MEANS OF AIRBORNE LIDAR **c43**

Alexander P. Vasilkov, Yuri A. Goldin, and Boris A. Gureev *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1122-1126 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

It has been theoretically shown that light scattering coefficient (B) dependence on depth (Z) can be derived from temporal dependence of backscattered pulse polarization degree when sounding sea water by linear polarized light pulses. Experimental examination of the method is carried out by using an airborne lidar at the altitude 300 m (5 mW of sounding pulse power, 5 nsec in pulse duration, 532 nm in radiation wavelength, and 10-40 mrad in field of view). Backscattered pulse depolarization degree variation from 0 to 6 percent at the interval 0-200 nsec was determined. Qualitative agreement of the determined dependence B(Z) with that measured by an underwater device from the research vessel, good reproduction of B(Z) for different return signals at the same region, and clear distinctions for different regions are obtained. Behavior of the Kuroshio Warm-Core Rings (KWCR) in the southern Kurils area is studied using NOAA satellite infrared (IR) images for the period of 1986-1991. Six rings were traced entering the area and moving northeastward along the coastline. It was found that they can reach the traverse of Urup Island preserving a core of modified Kuroshio water.

Hydrographic fronts and warm and cold water streamers associated with rings are supposed to determine the Pacific saury and sardine distribution. A stable accumulation of fish schools is shown at the northern edge of a ring and in a low temperature interior part. Ring influence on a position and intensity of cold water offshore intrusions and branches of the Oyashio current, which control the fish migration routes, are supposed to be an important point in understanding a variability of conditions for commercial fishing in the area. The possibility of Rayleigh convection on the rotating earth in the deep-sea basins of the ocean has been theoretically studied using some observations. The study resulted in the following conclusions: (1) the resonance interaction of two modes of perturbation in abyssal trenches can lead to nonlinear instability which varies at different locations; (2) shift flux determined by a meridional temperature gradient is a destabilizing factor in Rayleigh instability; (3) meridionally oriented trenches are more 'dangerous' for instability initiation than those oriented latitudinally; (4) the calculated profiles of velocity components of tidal flux in the bottom layer is consistent with real observations; (5) vertical profiles of friction tensions happen to be nearly linear downward; (6) conditions of dynamic stability of bottom layer waters of the trenches are rather tidal cycle sensitive; (7) a complicated dynamic interaction in trenches should change critical parameters of 'convection with velocity shift' in tidal cycle than in the case of Rayleigh convection on rotating earth; (8) advective shift flux induced by meridional temperature gradient influence a dynamic stability in bottom layers of meridionally oriented trenches and results in change of periodicity in Richardson number temporal variability; and (9) presence of well-pronounced and determined component and variability of dynamic stability of bottom waters of trenches suggests a possibility of forecasting fine structure development in them by this method. It is believed that the above result will be applicable for describing tidal phenomena and can solve disputable problems concerning the scales of bottom convection development and determining its critical parameters. The ocean surface state, changing mainly because of wind action, determines the intensity of the scattered radar signals and makes the basic contribution in the underwater noise level. Dimensions of a ground resolution of the OKEAN satellite side looking radar operating at X band and a listening area of the ocean noising surface at kilohertz frequencies are commensurable with each other. These features permit estimates of the noise intensity by the satellite radar data. The radar images of regions with strong winds, sharp wind speed gradients, and mesoscale regulated structures are used to analyze the spatial distribution of ambient noise. Author (NASDA)

Remote sensing of the surface manifestation of internal waves and film slicks were carried out by Ka-band radar with a frequency 37 GHz. Observations of the radar backscattering were accompanied by measurements of the wavenumber spectrum of wind waves within the 6-120 cm wavelength range. Variability of the radar signals due to internal waves and slicks has been shown to exceed variability of the spectrum of short wind waves with decimeter-centimeter (dm-cm) wavelengths. This effect can be interpreted on the base of mechanism of 'parasitic' capillary ripple generated by dm-cm waves near their crests. Author (NASDA)

Improved accuracy and quality of interpretation of satellite imagery in the marine observation may be obtained by using the Optical Transfer Operator (OTO) of the Atmosphere-Ocean System (AOS) illuminated by a solar beam. Solar radiation transfer is described by two models, the atmosphere-surface model and the atmosphere-ocean model with reflective and refractive interface. Operators to express reflection and refraction of the interface are defined. Three problems of radiative transfer are considered for calculating the sunlight intensity field in the atmosphere-ocean system: the ocean-surface, atmosphere-ocean system with later homogeneous interface, and the atmosphere-ocean with later homogeneous interface, including the effects of the ocean waves. In the first stage, the atmosphere influence functions are defined. In the second stage, the optical transfer operator, which establishes the obvious connection with the radiation interaction law at the boundary, is calculated. Basic theoretical tools needed to solve the three-dimensional radiative transfer with the reflective and refractive interface is obtained in form of the linear vector-functional equation. CLOUD LIQUID WATER CONTENT OVER THE PACIFIC OCEAN TROPICAL ZONE DERIVED FROM SHIP MICROWAVE RADIOMETRIC MEASUREMENT **c47**

L. M. Mitnik, M. L. Mitnik, and M. Yu. Shoom *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1160-1165 (For primary document see N94-12635 01-42)

Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Measurements of the brightness temperatures from the research vessels at wavelengths 2.3 cm and 1.35 cm during ten cruises permitted investigation of the spatial variability of total cloud liquid water content Q. Values of Q were estimated by the brightness temperature difference of the cloudy and cloudless atmosphere delta T(sub B). The microwave measurements were accompanied by hydrometeorological and radar ones and radiosonde sounding. The delta T(sub B) and Q profiles obtained at crossing of a tropical depression are analyzed. Ship data for the atmospheric front and radiative transfer model are used to simulate future multichannel microwave measurements from the orbital station MIR ('Priroda' project) and to investigate the effect of antenna smoothing. VARIABILITY OF SPECTRAL REFLECTANCE IN COASTAL WATERS NEAR THE RIVER PLUMES **c43**

Vladimir I. Burenkov and Alexander P. Vasilkov *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1166-1170 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

Because of great difference in optical properties of river and sea waters, optical remote sensing is very effective for investigation of river plumes and their dynamics. The results of shipboard measurements of spectral reflectance in coastal waters near mouths of different rivers are described. Vertical profiles of the beam attenuation coefficient are also considered. Due to the high concentration of suspended matter in river waters, the value of spectral reflectance in blue and green regions of the spectrum in river plumes was anomalous and came to 20 percent. River waters were separated from surrounding sea waters by intensive fronts in which the value of spectral reflectance diminished by three-four times. This reduction was greater in red and green parts of the spectrum than in blue. Sometimes diffusive zones of mixing of river and sea waters existed. Spatial distribution of spectral reflectance inside the river plumes was very heterogeneous. Often the system of internal fronts was observed. Also, quasiperiodic structures connected with short-period internal waves took place. Vertical profiles of water transparency showed that the thickness of the turbid water layer inside the river plume was about a few meters. Below the layer of turbid water, optical properties inside and outside the river plumes, essentially, didn't differ. Author (NASDA)

RADAR OBSERVATION OF INTERNAL WAVES FIELD IN THE NORTH-WEST PACIFIC **c43**

Andre V. Smirnov and Valentin S. Etkin *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1178-1183 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

This study represents the remote sensing investigation of surface manifestations of internal waves in the northwest Pacific in different seasons. Two radars were involved in the experiments: aircraft Real Aperture Radar (RAR) (2 cm in wavelength) and satellite Synthetic Aperture Radar (SAR) ALMAZ-1 (10 cm in wavelength). The analysis of RAR-images on two polarizations and SAR-image on only Horizontal Transmission Horizontal Reception Mode (HH)-polarization permitted interesting physical phenomena on images which may be visible or invisible, depending on radio wavelength, the angle of incidence, polarizations, and velocity of sensor's carrier. The investigation of the surface manifestations and of the interaction between internal and surface waves using radar and optical surveys are discussed. The oceanic waveguide propagation of short internal waves in seasonal thermocline and the waveguide's conversion in an open resonator with the aid of internal waves in the main thermocline are assumed. Some ideas are discussed about a possible increase in the Q-factor of the resonator, about the amplification of internal waves in the seasonal thermocline, and their surface manifestations. TRAJECTORY CURVING IN UNDERWATER PROPAGATION OF LIGHT **c74**

V. S. Remizovich, D. B. Rogozkin, and Sh. A. Shekhmametyev *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1184-1188 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

A problem of the optical radiation transmission through a thick layer of the ocean water is considered. An analytical description of the radiance distribution taking into account features of the oceanic phase functions is developed. The small-angle solution of the radiative transfer equation is modified by a self-consistent calculation procedure of the photon diffusion coefficient. The new parametric forms for the in-water radiance distribution parameters are found. The obtained solution provides good quantitative agreement with the experimental and numerical data. The shipboard computer system, designed for acquiring and processing satellite and in-situ hydrometeorological data and being operated on board R/V (Research Vessel) AKADEMIK KOROLEV is outlined. The system is composed of subsystems for processing the medium and high resolution data from NOAA satellites, Meteorological Satellite (METEOR), the Geostationary Meteorological Satellite-4 (GMS-4) and so forth, in-situ aerological probing data, and in-situ hydrological probing data, and meteorological data. Wide experience of Automatic Picture Transmission (APT)-data processing for calculating the Sea Surface Temperature (SST) fields and for reconstructing the currents by sea marker tracing were planned, and during two marine expeditions, the experiments laying out the system on a ship compactly and subsurface eddy observation were carried out successfully. Recent activities for utilization of the system are introduced. Author (NASDA)

An atmospheric attenuation model is derived for average conditions and used to determine an optimal form of SST (Sea Surface Temperatures) retrieval algorithms for AVHRR (Advanced Very High Resolution Radiometer) data depending on region and season. Since multi-viewing angle SST measurements are found to be important for accurate SST retrieval, a statistical method of obtaining this information from collection of AVHRR imagery for about 10 days is described. As on the same data set, an extrapolation to zero cloudiness by means of quantile estimators is also possible. A combined technique is suitable for average SST field determination in cloudy conditions common to the North Pacific in winter. Author (NASDA)

Microprocessing and computer-based instrumentation have recently become more prevalent in oceanological studies. Specific features of deep-water measurements make it necessary to find an adequate telemetry system structure which has to satisfy the whole group of contradictory demands. This paper is dedicated to some aspects of elaboration on the hydrophysical measuring systems structure. The structure can be applicable for the data acquisition and processing of vertical sounding and of self-contained stations. Particular care has been taken in designing underwater devices. Two types of hydrophysical instruments were built upon the structure base: a multichannel sonde and a self-contained current meter. Author (NASDA)

A coupled barotropic model of the South China Sea (SCS) is presented. The first part includes a geostrophic model which was used to study emerging or changing large-scale organized currents under the influence of stochastic excitation to simulate the wind action on the surface and some other physical mechanisms. The second part is based on the shallow water equations. It can be used for assimilating altimetric data simulated with the first part and for calculating the velocity field. This part of the model was also used for independent analysis of wind driven circulation in the SCS. Author (NASDA)

Based on ocean-surface-temperature and atmospheric-pressure satellite data, the main physical fields of the western Pacific are reconstructed with the help of mathematical models. Statistics of subsequent scripts created for medium state are used for forecasting the thermodynamic structures and biota behavior with the help of adaptive learning models. Mathematical formulation of the problem is given. Results of numerical experiments in the western Pacific and the subarctic front area are analyzed. Author (NASDA)

Dynamic structures of the subarctic zone in the western Pacific are studied on the base of a quasi-geostrophic baroclinic model with the help of satellite data on the ocean surface temperature. The calculated fields of zonal components for full fluxes and the transport stream function are used to diagnose and recognize the variability of the Subarctic Front (SF) and Kuroshio Front (KF) on synoptical time scales with decadal discreteness. It is shown that the characteristic peculiarity of the Subarctic Frontal Zone (SAFZ) is the horizontal alternation of zonal countercurrents, on the margins of which the conditions are created for generating the baroclinic vortices and fronts; the thermal SF is more vividly exposed on the Kuroshio northern branch periphery and in the place of the subarctic current adjoining the Emperor Mounts. It is stated that the temperature field of the SAFZ water surface preserves the information on the bottom relief of the region. Author (NASDA)

Important problems of environment control demand elaboration of remote methods for Dissolved Organic Matter (DOM) diagnostics in natural water. Currently, fluorescent methods using a Raman scattering signal as an internal standard are widely applied for environment control DOM in water. The most difficult problems arising during fluorescent monitoring of natural sea and river water are: (1) the correlation between fluorescent intensity (I(sub fl)) and DOM concentration (C); (2) taking into account the natural temperature variations and ultraviolet sunlight radiation; and (3) the influence of Ultraviolet (UV) laser excitation on DOM fluorescence. This paper represents the results of a study of the fluorescence of natural DOM. Experimental study of the influence of temperature and sunlight UV irradiation on the fluorescence signal of DOM has been carried out in this study. The features of fluorescence spectra of DOM under UV laser excitation (the effect of fluorescence saturation and photo-chemical destructions) have been observed. The optimal regime of spectra detection is under consideration. The recommendations on laser remote sensing of organic pollutions in water have been given (wavelength of excitation and experimental conditions). Author (NASDA)

Surface Enhanced Raman Scattering (SERS) for organic molecules dissolved in the sea water has been reviewed for the first time. An increase in the intensity of Raman lines by a factor of 10(exp 6), in the case of the surface enhancement, gives the new sensitive method of pollution monitoring. SERS spectra for aqueous solutions of oil components in the sea water were observed. Dependence of SERS intensity on concentration of pollution has been obtained. SERS intensity of the H2O band as an internal standard for measurement of pollution concentration has been used.

Possibile formation of fish concentrations on the north and south divisions of the polar front (NPF (Northern Polar Front) and SPF (Southern Polar Front)) is investigated according to the data of vertical water structure, plankton community state, and epipelagic fish distribution using the acoustic method in the North Korean and Russian exclusive zone. Both NPF and SPF had considerable inclination. Downwelling was observed near the surface front and upwelling was in the back part of these zones. The productivity of plankton in the NPF and SPF zones was higher than that in subarctic and interfrontal zones. The sparse fish concentrations (sardine, Japanese anchovy, pacific mackerel, Japanese pearlside, round-herring, and squids) were arranged as almost continuous striples in the back parts of both frontal zones, increasing from one to five shoals per nautical mile in the areas of meandering NPF and SPF. It is supposed that high productivity of plankton due to nutrients influx in upwellings is the reason for fish concentrations in the SPF and NPF zones. This concentration forms on the warm sides of thermal fronts. The location of these fronts may be rather easily defined on the satellite infrared images of the ocean surface.

HIGH BIOLOGICAL PRODUCTION OF THE TIDAL MIXING ZONES ON JAPAN SEA SHELF **c51**
Yury I. Zuenko *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1240-1244 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The seasonal variation of summary plankton production is considered according to the observational data from summer-autumn 1989-1990 in the northwestern part of the Sea of Japan. In stratificated offshore waters, the low productivity (P/B (Daily Production per a Unit of Biomass) 0.2 d(exp -1)) was observed in July-August. It grew in September, especially in October (to 1 to 3 d(exp -1)). In the tidal mixing zones on shelf with weakened stratification, the period of low productivity was shorter: from the middle of July to the middle of August. The reason for these peculiar tidal mixed zones is an uninterrupted nutrient influx to the euphotic layer, that becomes weak in the time of the highest heating only. Everywhere in the north-western part of the sea, the autumn bloom of phytoplankton begins in September, owing to a wind-wave stirring, with addition of an upwelling effect near the Prymorye Coast in October-November. When the plankton production is low offshore but still (or already) high in the tidal mixing zones, plankton-eating fishes (such as sardine) concentrate in this zone on the shelf.

This paper presents the results of a study on drifter paths calculated from a simplified kinematic model. The problem of horizontal diffusion, stirring, and mixing processes parameterization in open ocean mesoscale currents is under discussion. Appropriate formulas are proposed from the model. It is shown that the most effective diffusion corresponds to instationarity regime when eddies evolution time is comparable with time of half of particle circuit around eddy center. It is also learned that believing intervals of diffusion coefficient K are always greater than K itself; hence, its traditional parameterization can be used only when the roughness of the K definition cannot influence the study results. The original approach formulates a task for stirring exponent definition. In the presence of molecular diffusion, the balance between stirring and mixing results in filaments of stable scale in the tracer field. Mathematical modeling of drifter ensemble spreading over a large-scale basin shows that the most homogeneous drifter set can be obtained by their initial deployment in frontal and vortical active areas.

The algorithm for primary production determination from satellite data is proposed. The algorithm consists of the steps such as the following: (1) data acquisition of the upwelling radiance spectrum from satellite data; (2) atmospheric correction; (3) estimation of approximate chlorophyll content in the surface sea layer by means of solving the 'inverse problem of hydro-optics'; (4) more precise determination of chlorophyll using relations between this one, pigment index, and light absorption by phytoplankton pigments; (5) determination of underwater fields of irradiance by means of optical classifications of the ocean waters; (6) estimation of light energy absorbed by phytoplankton using typical profiles of chlorophyll, its relation to light absorption by pigments, and taking into account other light-absorbing components of sea water; (7) determination of primary production, based on preliminary study of light dependence of the quantum yield of marine photosynthesis and parameters obtained according to points five and six; and (8) verification, integration of results, and their correction. The structure of the algorithm makes it possible to modify relevant relationships in response to the experimental information.

PROBLEM OF CLIMATE CHANGE PREDICTABILITY AND SATELLITE RADIATION BUDGET OBSERVATIONS c47
Vladimir V. Kozoderov *In* Scientific Organizing Committee of PORSEC, Proceedings of the PORSEC 1992 in Okinawa: Conference for Pacific Ocean Environments and Probing, Volume 2 25 Aug. 1992 p 1288-1292 (For primary document see N94-12635 01-42)
Copyright Avail: Issuing Activity (Scientific Organizing Committee of PORSEC, P.O. Box 10, Shimizu, Shizuoka 424, Japan, HC)

The predictability problem for climate change is considered as that of signal to noise ratio calculated using satellite temporal data sets of the earth radiation budget components. In these ratios, the signal is characterized by cross-correlations of outgoing longwave radiation anomalies and noise by the standard deviations of the anomalies. To develop such a scientific approach, a concept of energy active zones of the world ocean has been elaborated based on results of monitoring and modeling. The approach using principal component techniques and climate indices enables satellite remote sensing data and measurements from scientific vessels to be linked in order to develop dynamical models of the ocean. A METHOD FOR CALCULATING EXACT GEODETIC LATITUDE AND ALTITUDE
Isaac Sofair Mar. 1993 18 p
(AD-A265783; NSWC-TR-85-85-Rev) Avail: CASI HC A03/MF A01

This report derives a new and improved technique for computing the geodetic latitude and altitude of an arbitrary point in space assuming the Earth is an ellipsoid of revolution. This method theoretically computes the exact values of the geodetic latitude and altitude. All the programs currently in use utilize approximation techniques for computing the quantities mentioned above. The method is simple and efficient and is strongly recommended for implementation. RETRIEVAL OF RADIATION BUDGETS IN THE ARCTIC FROM SATELLITE MEASUREMENTS Ph.D. Thesis
Zhanqing Li 1991 200 p
Avail: Univ. Microfilms Order No. DANN72022

This study addresses the problems associated with each step of the process of retrieving radiation budgets at the top of atmosphere (TOA) and at the surface from satellite measurements in the Arctic. The data used are from the Earth Radiation Budget Experiment (ERBE) radiometer and Advanced Very High Resolution Radiometer (AVHRR), together with radiative transfer calculations. The limitations of the ERBE scene identification algorithm when applied to observations in the Arctic are investigated by comparing the scenes identified by ERBE with simultaneous and colocated AVHRR-based scenes. Considerable discrepancies are found, especially the misidentification by the ERBE scene identification method of clear fractional ice as being partly cloudy skies over open water. More accurate TOA fluxes and cloud forcing in the Arctic are derived by taking advantage of the broadband radiance measurements made by the ERBE radiometer and the more reliable scene identification deduced from narrow band multi spectral measurements made by the AVHRR. Comparisons of the cloud forcing determined from the two scene identification methods show differences as large as 50 Wm(exp -2) in some regions of the Arctic. The validity of the ERBE angular dependence models (ADMs) is also evaluated in the Arctic. It is found that the ADM for clear ice/snow is not reliable when applied in the Arctic during summer. The ADM for overcast skies contains systematic errors when applied to overcast conditions over ice/snow surfaces. The systematic error is removed by modifying the ADM. To estimate the surface absorbed flux from reflected flux at the TOA, a simple parameterized model is developed based on comprehensive radiative simulations. The model is independent of cloud optical thickness, surface type, and has only a moderate dependence on the presence or absence of cloud, cloud type and water vapor, but a strong dependence on solar zenith angle (SZA). Surface absorbed fluxes determined by radiative transfer calculations may generally be estimated to within 10 W m(exp -2) by the simple model from TOA reflected fluxes with knowledge of the SZA and precipitable water. Finally, narrowband-to-broadband reflectance conversion is carried out with careful attention paid to a particular statistical problem, namely, regression analysis with spatially autocorrelated satellite measurements. Both scene-dependent and scene-independent regressional models are developed to estimate broadband reflectance from the narrow band reflectances in channels 1 and 2 of AVHRR. The RMS errors in the percentage reflectances from the scene-dependent models are 1.0, 1.8, 2.0 and 3.1 for the ocean, land, ice/snow and cloud, respectively. Except for land, the scene-independent model does virtually as good a job as the scene-dependent models. Author

ESTIMATING PHOTOSYNTHETICALLY AVAILABLE RADIATION (PAR) AT THE EARTH'S SURFACE FROM SATELLITE OBSERVATIONS
Robert Frouin *In its* Studies of the Net Surface Radiative Flux from Satellite Radiances During FIFE 14 Jun. 1993 p 28 Submitted for publication (For primary document see N94-10953 01-43)
Avail: CASI HC A03/MF A02

Current satellite algorithms to estimate photosynthetically available radiation (PAR) at the earth' s surface are reviewed. PAR is deduced either from an insolation estimate or obtained directly from top-of-atmosphere solar radiances. The characteristics of both approaches are contrasted and typical results are presented. The inaccuracies reported, about 10 percent and 6 percent on daily and monthly time scales, respectively, are useful to model oceanic and terrestrial primary productivity. At those time scales variability due to clouds in the ratio of PAR and insolation is reduced, making it possible to deduce PAR directly from insolation climatologies (satellite or other) that are currently available or being produced. Improvements, however, are needed in conditions of broken cloudiness and over ice/snow. If not addressed properly, calibration/validation issues may prevent quantitative use of the PAR estimates in studies of climatic change. The prospects are good for an accurate, long-term climatology of PAR over the globe. Author (revised)

A summary of the results of the pre-operation analysis is presented and includes the following: (1) detailed analysis of ground station antenna pointing errors at the tracking and data acquisition stations in and out of the country and overseas portable tracking stations during the satellite's critical phase; and (2) the launch and early orbit phase and RSP (Receiver Signal Processor) maintenance analysis during the satellite mission duration of the JERS-1 (Japanese Earth Resources Satellite-1). The result of both analyses, azimuth to elevation and azimuth to time errors for each station for the former and the RSP maintenance limits, eccentricity maintenance limits, number of controls, and propellant weight required in four cases of atmospheric model error estimation are shown. TOVS SOUNDINGS: IMPACT ON THE SYNOPTIC ANALYSIS OVER THE SOUTH AND SOUTHEAST REGIONS OF BRAZIL FROM MARCH 18 TO MARCH 19, 1991 M.S. Thesis [SONDAGENS TOVS: IMPACTO NA ANALISE SINOTICA ENTRE 18 E 19 DE MARCO DE 1991 NA REGIAO SUL E SUDESTE DO BRASIL]
Jojhy Sakuragi Nov. 1992 151 p In PORTUGESE
(INPE-5497-TDI/512) Avail: CASI HC A08/MF A02

This report explores the impact of temperature and humidity profiles retrieved from radiances obtained by TIROS Operational Vertical Sounder (TOVS) on the synoptic analysis over South and Southeast of Brazil. The radiance data obtained by the TOVS sounder which operates on board of the TIROS-N/NOAA polar orbiting meteorological satellites were processed with the aid of the International TOVS Processing Package-4 (ITPP-4), numerical analyses from National Meteorological Center (NMC), and conventional meteorological data. From the temperature and humidity profiles initially obtained, temperature, geopotential height, precipitable water, instability index, and advection fields were generated at constant pressure levels. A case study of the occurrence of intense precipitation during 19 March, 1991, in the Greater Sao Paulo and nearby coastal regions, was so formed. The results were compared with the NMC analyses and the meteorological conditions observed in the satellite imagery. Based on these results, it is generally concluded that the impact of satellite data is positive, especially due to its availability over the oceanic regions, and by the high spatial resolution and high temporal frequency. The good agreement between the TOVS results and the observed meteorological conditions from satellite images supports this conclusion. Author (revised)

AN EXPERT SYSTEM SHELL FOR INFERRING VEGETATION CHARACTERISTICS: PROTOTYPE HELP SYSTEM (TASK 1)
Jul. 1993 24 p
(Contract NAS5-30127)
(NASA-CR-193411; NAS 1.26:193411; C931032-U-2R08) Avail: CASI HC A03/MF A01

The NASA Vegetation Workbench (VEG) is a knowledge based system that infers vegetation characteristics from reflectance data. A prototype of the VEG subgoal HELP.SYSTEM has been completed and the Help System has been added to the VEG system. It is loaded when the user first clicks on the HELP.SYSTEM option in the Tool Box Menu. The Help System provides a user tool to support needed user information. It also provides interactive tools the scientist may use to develop new help messages and to modify existing help messages that are attached to VEG screens. The system automatically manages system and file operations needed to preserve new or modified help messages. The Help System was tested both as a help system development and a help system user tool. ENHANCEMENT EFFECTS IN POLARIMETRIC RADAR RETURNS: PHASE DIFFERENCE STATISTICS
R. H. Lang and N. Khadr 1993 4 p
(Grant NAG5-1807)
(NASA-CR-193408; NAS 1.26:193408) Avail: CASI HC A01/MF A01

The probability density functions (pdfs) of the co- and cross-polarized phase differences are derived for backscatter from vegetation using the coherent and incoherent scattering theories. Unlike previous derivations, no assumptions or observations other than the applicability of the Central Limit Theorem (CLT), the low fractional volume of the medium, the reciprocity of the scatterers, and the azimuthal symmetry of the scatterer's orientation statistics are employed. Everything else follows logically via the mathematics. The difference between the coherent theory and the incoherent theory is referred to as the backscatter enhancement effect. The influence of this enhancement effect on the phase difference pdfs is examined and found to be important under combined conditions of scatterer anisotropy and appropriate reflection coefficient values. APPLICATION OF THE AIRBORNE OCEAN COLOR IMAGER FOR COMMERCIAL FISHING
Robert C. Wrigley Mar. 1993 81 p Original contains color illustrations
(RTOP 142-20-37)
(NASA-TM-103986; A-93005; NAS 1.15:103986) Avail: CASI HC A05/MF A01; 8 functional color pages

The objective of the investigation was to develop a commercial remote sensing system for providing near-real-time data (within one day) in support of commercial fishing operations. The Airborne Ocean Color Imager (AOCI) had been built for NASA by Daedalus Enterprises, Inc., but it needed certain improvements, data processing software, and a delivery system to make it into a commercial system for fisheries. Two products were developed to support this effort: the AOCI with its associated processing system and an information service for both commercial and recreational fisheries to be created by Spectro Scan, Inc. The investigation achieved all technical objectives: improving the AOCI, creating software for atmospheric correction and bio-optical output products, georeferencing the output products, and creating a delivery system to get those products into the hands of commercial and recreational fishermen in near-real-time. The first set of business objectives involved Daedalus Enterprises and also were achieved: they have an improved AOCI and new data processing software with a set of example data products for fisheries applications to show their customers. Daedalus' marketing activities showed the need for simplification of the product for fisheries, but they successfully marketed the current version to an Italian consortium. The second set of business objectives tasked Spectro Scan to provide an information service and they could not be achieved because Spectro Scan was unable to obtain necessary venture capital to start up operations. [GLOBAL MONITORING OF ATMOSPHERIC PROPERTIES BY THE EOS MODIS] Semiannual Technical Report, Jan. - Jun. 1993
Michael D. King 1993 20 p Original contains color illustrations
(NASA-TM-109237; NAS 1.15:109237) Avail: CASI HC A03/MF A01; 2 functional color pages

The Moderate Resolution Imaging Spectroradiometer (MODIS) being developed for the Earth Observing System (EOS) is well suited to the global monitoring of atmospheric properties from space. Among the atmospheric properties to be examined using MODIS observations, clouds are especially important, since they are a strong modulator of the shortwave and longwave components of the earth's radiation budget. A knowledge of cloud properties (such as optical thickness and effective radius) and their variation in space and time, which are our task objectives, is also crucial to studies of global climate change. In addition, with the use of related airborne instrumentation, such as the Cloud Absorption Radiometer (CAR) and MODIS Airborne Simulator (MAS) in intensive field experiments (both national and international campaigns, see below), various types of surface and cloud properties can be derived from the measured bidirectional reflectances. These missions have provided valuable experimental data to determine the capability of narrow bandpass channels in examining the Earth's atmosphere and to aid in defining algorithms and building an understanding of the ability of MODIS to remotely sense atmospheric conditions for assessing global change. Therefore, the primary task objective is to extend and expand our algorithm for retrieving the optical thickness and effective radius of clouds from radiation measurements to be obtained from MODIS. The secondary objective is to obtain an enhanced knowledge of surface angular and spectral properties that can be inferred from airborne directional radiance measurements. Author

SATELLITE INVENTORY OF MINNESOTA FOREST RESOURCES Final Report
Marvin E. Bauer, Thomas E. Burk, Alan R. Ek, Pol R. Coppin, Stephen D. Lime, Terese A. Walsh, David K. Walters, William Befort (Minnesota Dept. of Natural Resources, Grand Rapids.), and David F. Heinzen (Minnesota Dept. of Natural Resources, Grand Rapids.) Jul. 1993 27 p Original contains color illustrations
(Grant NAGw-1431)
(NASA-CR-193565; NAS 1.26:193565; NRA-87-106) Avail: CASI HC A03/MF A01; 3 functional color pages

The methods and results of using Landsat Thematic Mapper (TM) data to classify and estimate the acreage of forest covertypes in northeastern Minnesota are described. Portions of six TM scenes covering five counties with a total area of 14,679 square miles were classified into six forest and five nonforest classes. The approach involved the integration of cluster sampling, image processing, and estimation. Using cluster sampling, 343 plots, each 88 acres in size, were photo interpreted and field mapped as a source of reference data for classifier training and calibration of the TM data classifications. Classification accuracies of up to 75 percent were achieved; most misclassification was between similar or related classes. An inverse method of calibration, based on the error rates obtained from the classifications of the cluster plots, was used to adjust the classification class proportions for classification errors. The resulting area estimates for total forest land in the five-county area were within 3 percent of the estimate made independently by the USDA Forest Service. Area estimates for conifer and hardwood forest types were within 0.8 and 6.0 percent respectively, of the Forest Service estimates. A trial of a second method of estimating the same classes as the Forest Service resulted in standard errors of 0.002 to 0.015. A study of the use of multidate TM data for change detection showed that forest canopy depletion, canopy increment, and no change could be identified with greater than 90 percent accuracy. The project results have been the basis for the Minnesota Department of Natural Resources and the Forest Service to define and begin to implement an annual system of forest inventory which utilizes Landsat TM data to detect changes in forest cover. LANDSAT AS A COMMERCIAL ENTERPRISE M.S. Thesis
Maria Carmen deMello Lemos 1992 62 p
(INPE-5477-TAE/019) Avail: CASI HC A04/MF A01

In 1985 the government of the United States signed a contract with the Earth Observation Satellite Company (EOSAT) transferring the operation and future development of the country's earth resources observation system, the Landsat. The objective of this study is to discuss the commercialization of the Landsat system in light of its economical and political implications, mainly concerning international relations, security and the U.S. leadership in space technology. The commercialization allegedly goals were mainly to establish a strong market for Landsat data and to cut government's support for operations and construction costs. So far neither goal was satisfactorily met. The general conclusion of this study is that the Landsat transfer to the private sector was much more motivated by budget cuts than by the real possibilities of Landsat surviving as a private enterprise. As a consequence, the Landsat program has been seriously threatened of termination in the past 5 years with dramatic political, social and economical consequences to the United States. Author

This is the final report for a study performed for the 1992 LDRD spaceborne SAR (Synthetic Aperture Radar) study. This report presents an overview of some of the issues that must be considered for design and implementation of a SAR on a spaceborne platform. The issues addressed in this report include the following: a survey of past, present, and future spaceborne SARs; pulse-repetition frequency (PRF); general image processing issues; transmitter power requirements; the ionosphere; antennas; two case studies; and an appendix with a simplified presentation on geometry and orbits. Some of the features of the air sea ice interaction processes and the characteristics of sea ice relative to applications of remote sensing techniques are described qualitatively. The polar regions play an important role in the global climate mechanisms since generally they act as heat sinks in the large scale atmospheric circulation. In this context the polar oceans interact with the atmosphere in the way that sea ice forms over large areas and thereby, reduces the heat exchange between the ocean surface and the atmosphere. Sea ice also interacts with the ocean in a number of ways so that we are faced with a rather complex air sea ice interaction problem. This is subject to research in order to be able to arrive at a good understanding of the phenomena observed with a view to applications in global climate studies including numerical modeling. Remote sensing is used extensively and at an increased rate after the launch of ERS-1 which offers fine resolution SAR (Synthetic Aperture Radar) data independent of cloud and light conditions. Examples of observations are given and the role of ERS-1 in polar ocean research is discussed. ESA

In a period of 8 months after the launch of the ERS-1 satellite, the wind scatterometer has been calibrated to an absolute level of 0.2 dB, using transponders and the stable backscattering of the tropical rain forest. With the support of the scientific user community, a program of geophysical validation and model tuning was carried out based on meteorological model analysis and high quality surface observations. After one year in orbit, the ERS-1 wind product has achieved a high level of accuracy. Supporting work on ice mapping is reported. ESA

The 1991 ESA experimental campaign 'RENE91' was meant to calibrate and validate (Cal/Val) ERS-1 ocean data and geophysical products. For a number of days during this campaign, directional ocean wave spectra were measured concurrently by the ERS-1 in AMI (Active Microwave Instrument) image mode; by the airborne SAR (Synthetic Aperture Radar), 'PHARS' (Phased Array SAR); by the shipborne radar 'SHIRA'; and by a Datawell wave buoy. The results of these instruments are compared and qualitatively interpreted on the basis of SAR ocean wave imaging theory. It is found that: very short (less than 70 m) waves are not seen by ERS-1, nor by PHARS; roughly half the wave occurrences are detected by both ERS-1 and PHARS, the remaining are missed by either or both; peak wavelength and direction of the same wave component can differ considerably as imaged by the various sensors; and ERS-1 has more difficulty detecting wave systems than the other sensors, especially azimuth traveling ones. All these effects can be understood in terms of the elements of the SAR ocean wave imaging process, viz scanning distortion, velocity bunching, and defocussing. ESA

As part of the ERS-1 validation program, the ERS-1 Synthetic Aperture Radar (SAR) wave spectra validation experiment was carried out over the Grand Banks of Newfoundland (Canada) in Nov. 1991. The principal objective of the experiment was to obtain complete sets of wind and wave data from a variety of calibrated instruments to validate SAR measurements of ocean wave spectra. The field program activities are described and the rather complex wind and wave conditions which were observed are summarized. Spectral comparisons with ERS-1 SAR image spectra are provided. The ERS-1 SAR is shown to have measured swell and range traveling wind seas, but did not measure azimuth traveling wind seas at any time during the experiment. Results of velocity bunching forward mapping and new measurements of the relationship between wind stress and sea state are also shown. ESA

ERS-1 SCATTEROMETER DATA CHARACTERISTICS AND WIND RETRIEVAL SKILL

Ad Stoffelen and David L. T. Anderson (Oxford Univ., England.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 41-47 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Calibration and validation activities for the ERS-1 scatterometer have been carried out at ECMWF (European Center for Medium range Weather Forecasting), where a wealth of verifying data is available both in time and space for satellite instrument calibration and validation. It is shown that measurement noise is sufficiently low that a solution surface is generally well defined in three dimensional measurement space except at the inner edge of the swath and a low wind speed. Based on the ECMWF analyses, ESA's prelaunch transfer model CMOD2 was reformulated (denoted CMOD3 by ESA) and some further improvements in bias and wind direction sensitivity subsequently made (CMOD4). Based on the new transfer function, a revision of the existing wind retrieval scheme used by ESA is proposed. ESA

VALIDATION OF ERS-1 WIND AND WAVE DATA BY USE OF OPERATIONAL FORECAST MODELS

Lars-Anders Breivik and Magnar Reistad (Norwegian Meteorological Inst., Bergen.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 49-53 (For primary document see N94-11704 01-43)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Since the launch of ERS-1 in Jul. 1991 scatterometer wind information and altimeter wave information from the North Atlantic has been received in real time at the Norwegian Meteorological Institute. The data has been collocated with and evaluated against operational numerical weather forecast model and sea wave model data. The wind scatterometer data are found to be capable of observing the surface wind field with high accuracy. The main problem is connected to obtaining the right wind direction in cases of rapid spatial variations in the wind field. The altimeter wave height data are good. Routines for assimilating the data in the numerical models were developed and are currently running in parallel with the operational routines. The average impact is modest, but there are cases of significant positive impact. ESA

A C-BAND WIND SCATTEROMETER MODEL DERIVED FROM THE DATA OBTAINED DURING THE ERS-1 CALIBRATION/VALIDATION CAMPAIGN

Volkmar Wismann *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 55-59 (For primary document see N94-11704 01-43)

(Grant BMFT-01-QS-90144)

Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The geophysical calibration and validation campaign for the first European Remote Sensing Satellite (ERS-1) took place in the Norwegian Sea between 15 Sep. - 10 Dec. 1991. Ocean surface wind measurements were carried out with the airborne C band scatterometer RACS of the University of Hamburg during 46 underflights of the satellite. The wind was measured by the navigational system of the Do-228 aircraft during low level (6 to 150 m) flights. A high quality subset of these data was used to tune the proposed wind scatterometer model function which differs from the ERS-1 prelaunch CMOD-2 formulation by an azimuth dependance of the wind speed exponent. A wind retrieval test demonstrates that the proposed model satisfies the ESA specifications for the ERS-1 wind scatterometer model. ESA

An account of the status of the project 'Aspects of ERS-1 LBR validation in the Mediterranean Sea' is given. The project is composed of two complementary activities: one devoted to experiments in the open sea measuring the C band radar backscattering, wind stress, and high frequency sea surface elevation; the other devoted to the scatterometer and altimeter data validation. The aim is to assess the dependences of the radar backscattering from the sea wave parameters using both the satellite and the platform data on one hand, and to validate the ERS-1 scatterometer wind fields in studying their mesoscale characteristics. Results of the experimental activity are only quoted; the reported examples of the ERS-1 scatterometer wind fields show that they are unsuitable to be used without a deep and systematic correction of the directions selected by the fast delivery algorithm. ESA

During a number of cruises to the Iceland-Faeroe frontal area suface meteorological data (wind velocity, air and sea surface temperature etc.) were collected. Data covering about eight weeks of different seasons and meteorological conditions are available and in situ winds are intended for comparison with scatterometer derived ones. Appropriate satellite data are not yet received. Five SAR (Synthetic Aperture Radar) images from Mar. 1992 were investigated for mesoscale variability. From CTD profiles, a correlation between dynamic height at the sea surface and the amplitudes of empirical orthogonal eigenfunctions of sound velocity profiles were found, which in principle, allows to observe subsurface sound velocity by altimetry. Backscatter cross section (sigma(sub 0)) measurements from the ERS-1 scatterometer are collocated with surface wind velocity data from operational Numerical Weather Prediction (NWP) analyses to yield a fully empirical C band model function. The empirical model does not obey a power law at speeds less than 5 m/s, and upwind/crosswind ratios are small for all incidence angles at low wind speeds and for small incidence angles at all wind speeds. Downwind sigma(sub 0) exceeds upwind values for incidence angles below approximately 28 degrees. The full ERS-1 scatterometer data set has been reprocessed using the NWP model function. ESA

A calibration exercise utilizing seven ascending repeat passes over the English Channel in conjunction with precise orbits, GPS (Global Positioning System) measurement, local levelling, tide gauge data, and geoid/ocean tide/storm surge models was carried out for Jan. - Mar. 1992. Precise orbits of +/- 5 cm radial accuracy was achieved due to the satellite flying near overhead of the Herstmonceux laser ranger. From a total of 76 calibration points, a mean height residual of -46.0 cm with a standard deviation of 10.8 cm was observed. The derived electronic bias of -46.0 cm +/- 11 cm can be compared to -19.2 cm as estimated from the dedicated calibration validation based on the Venice Tower experiment and -60 cm to -70 cm from various long-arc studies. MAPPING OF THE EAST AUSTRALIAN CURRENT WITH THE ERS-1 SAR AND SHIPBORNE STUDIES c48
C. S. Nilsson, P. Tildesley, and J. Peterson *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 95-100 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Seven ERS-1 SAR (Synthetic Aperture Radar) passes were acquired during the first two weeks of Nov. and three in Dec. 1991 over the western Tasman Sea and East Australian Current (EAC) area. The EAC is a strongly flowing western boundary current that displays strong baroclinic instability and is the principal dynamic feature in the study area. The principal aim of this experiment was to evaluate the usefulness of ERS-1 C-band SAR in mapping ocean currents. An Airborne Expendable Bathythermograph (AXBT) survey and research ship cruise provided surface truth data. In most of the SAR swaths studied to date, the current flow shows, to varying degrees, some sharp ridges of enhanced backscatter that are assumed to be related to current shear-wave interaction. The data show clear evidence of SAR sensitivity to natural surface organic films. In one instance, a cool stream of Southern Ocean water images in great detail on the SAR and it is deduced that natural surfactants are the controlling mechanism, given uniform wind conditions. Thus, ERS-1 SAR will probably correlate with ocean color and prove a useful tool for studies of oceanic mixing, particularly at higher latitudes. ESA

The program plans to use data from the ERS-1 SAR (Synthetic Aperture Radar), together with surface data, to show coastal circulation, mixing, and other features in regions of the east, west, and Hudson Bay coasts of Canada. Sufficient coverage is planned to assess the variation of feature visibility with season, and to determine the influence of wind speed and surfactants. The extent of the Canadian program is described, and sample images are presented. The variation of SAR signal level with wind speed and direction is discussed, based on images of a Vancouver Island study area. The present ESA model of wind induced C band backscatter appears to overestimate variation with wind direction at ERS-1 SAR incidence angles. Surfactant slicks are visible for wind speeds less than about 5 m/s. Internal wave patterns are visible at higher speeds. ESA

ESR-1 C band scatterometer winds for five days of Nov. 1991 were analyzed to study its impact on the analysis. The data was examined in association with the climatological information, synoptic charts, as well as the ship data from the GTS network. It is observed that the wind data distribution over the Indian Ocean, where no other data exists, is good. There are many locations having opposite wind directions which calls for improved data quality evaluation. Data of 28 Nov. was found to be the most consistent and was used in the Global Data Assimilation System (GDAS). ESA

The Norwegian Continental Shelf Experiment (NORCSEX 91) was conducted between 6-29 Nov. 1991 during the commissioning phase of ERS-1. In this period about 30 SAR (Synthetic Aperture Radar) scenes were obtained at a regular interval of three days. Complementary in situ observations of wind wave current and their interaction were collected from ship and moorings. The integrated data base reveal that SAR images express features associated with: mesoscale ocean current circulation pattern including frontal boundaries and eddies; slicks; internal waves; and rapid mesoscale wind field variations. The expressions of oceanic circulation features and slicks are limited by both high and low wind speed. These preliminary results are presented and discussed. ESA

SAR IMAGING OF DYNAMICAL FEATURES IN THE ENGLISH CHANNEL c48
Alison Scoon and Ian S. Robinson *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 119-124 Sponsored in part by Natural Environmental Research Council (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

ERS-1 Synthetic Aperture Radar (SAR) images of a study area in the central English Channel were examined in relation to the information which they contain about dynamical ocean features. After compression to 8 bits and block averaging to reduce speckle, the mean radar return from an offshore region with uniform backscatter was related to the wind and tidal conditions. Repeat images of inshore areas show that fronts between inshore and offshore and offshore water can be seen in many tidal states. Their location is consistent with numerical model predictions of tidal residual flows. Smooth slicks, regions of low backscatter, also appear to correlate with discharges from rivers and coastal outfalls. By examining several images, permanent bathymetric signatures can be distinguished from the quasi-permanent dynamical and ephemeral features, pointing to a useful role for routine SAR monitoring for coastal management studies. EFFECTS OF WAVE NONLINEARITY ON ERS-1 RADAR ALTIMETER RETURNS: A PRELIMINARY INVESTIGATION **c48**
M. A. Srokosz and G. D. Quartly *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 125-130 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

A preliminary look at the sea state bias (due to wave nonlinearity) in ERS-1 radar altimeter measurements of sea surface topography is given. Using the limited amount of ERS-1 data available, the approach adopted is to choose occasions when the significant wave height changes over a short distance and to examine the corresponding change in the residual sea surface heights (obtained from the altimeter height measurements after applying various corrections and removing the orbit error and mean sea surface topography). The bias, as a percentage of significant waveheight, is found to vary from -1.7% to 9.4% with a mean value of 5.0%. The application of these results, to the correction of sea state bias in the ERS-1 altimeter height measurements, must be treated with caution due to the small number of cases studied here. ESA

SAR OCEAN IMAGING IN THE GULF OF ALASKA **c48**
O. H. Shemdin, D. W. Hayt, and D. P. Kasilingam *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 131-134 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Radar images of portions of the Gulf of Alaska acquired by the Synthetic Aperture Radar (SAR) aboard the ERS-1 platform are analyzed to extract qualitative and quantitative geophysical information. The primary objectives of this study are to investigate the imaging of ocean surface waves, ship wakes, and oil slicks. A preliminary version of a SAR image inversion model is used to obtain surface wave spectral information from the SAR images. Significant wave heights obtained from this technique agree well with in situ data obtained from buoys located near the image site. The images of ship wakes and oil slicks also provide useful qualitative information. ESA

A Jan. - Jun. 1992 10 m height wind vector field was computed with the CMOD2 model function. Freilich and Dunbar used ESA measurements of AMI (Active Microwave Instrument) sigma-naught to derive a refined model function and to produce an alternate Jan. - Jun. 1992 10 m height wind vector field, named FD data. The ESA and FD model functions and algorithms were substantially different. The FD wind vectors were in better agreement with the climatological mean wind field and with moored buoy wind measurements. The average correlation coefficients between monthly mean and daily averaged FD and moored buoy matchups of the Cartesian wind components were 0.84 and 0.74, respectively. The average root mean square differences between the monthly mean and daily averaged FD and moored buoy matchups of the Cartesian wind components were 1.25 and 3.0 m/s, respectively. ESA

COMPARISONS OF ERS-1 ALTIMETER HEIGHT DATA AND THE FINE RESOLUTION ANTARCTIC MODEL (FRAM)
H. M. Snaith and D. J. Webb (Institute of Oceanographic Sciences, Wormley, England.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 141-146 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Improvement in the understanding of the dynamics of the Southern Ocean is discussed. The Fine Resolution Antarctic Model (FRAM) was designed to help explain some of the dynamic mechanisms of the region and satellite altimetry offers a method of verifying the mesoscale activity of this large scale model. The study focuses on the Agulhas region. Comparisons of the FRAM surface dynamic height fields with historical data show that the major current systems are represented with reasonable accuracy. Geosat altimeter data were processed using a collinear technique to obtain sea surface height variability. The FRAM surface pressure fields were sampled as if by an altimeter and processed using the same collinear technique in order to gain an insight into errors involved in the method. The resultant variability fields are here compared with Geosat height variability and bathymetry. The same collinear technique was applied to ERS-1 altimeter data from the commissioning phase. ESA

ERS-1 PRELIMINARY ANTENNA ELEVATION PATTERN MEASURED BY GROUND-RECEIVERS
Pedro Seifert, Manfred Zink, and Harald Lentz (Stuttgart Univ., Germany.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 157-159 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

An approach to measure a SAR (Synthetic Aperture Radar) antenna elevation diagram which uses a greater number of high precision calibration receivers, lined up in cross track direction, to record azimuth slices of the antenna pattern, is described. The coregistration of the time of receipt, together with precise orbit and attitude data of the satellite, allows correlation of the azimuth cuts and calculation of adequate antenna elevation angles. As each of the received radar pulses is sampled 16 times, an examination of the pulse shape is also possible. The principle system is described and the preliminary result of the ERS-1 antenna elevation pattern measurement is presented. ESA

The preliminary results related to the ERS-1 AMI (Active Microwave Instrument) image mode data analysis carried out in the framework of the experiment I-7 are described. The SAR (Synthetic Aperture Radar) data was acquired during the 23 Oct. 1991 night pass over the Salento peninsula and the 21 Jun. and 7 Jul. 1992 day passes over the Matera area in southern Italy. In this experimental phase, the main objectives are the SAR image quality evaluation and calibration. To accomplish this, two active radar calibrators and several trihedral corner reflectors were deployed on both sites. A preliminary comparison with an available SAR omega-k processor is presented. During the period 26 Oct. - 2 Nov. 1991 a series of five consecutive ERS-1 SAR (Synthetic Aperture Radar) passes were underflown by the Canada Center for Remote Sensing CV 580 SAR system. In the airborne component of the experiment grids of nadir mode, C band VV polarized strip images were acquired along the ERS-1 SAR azimuth and range directions. The three coincident sets of ERS-1 and airborne SAR data acquired were analyzed to derive calibration functions for the Gatineau SGF products. The measured ERS-1 SAR antenna pattern is in good agreement with that reported by ESA. The calibration constant for the Gatineau SGF images was 61.3 +/- 0.45 dB with a residual uncertainly of +/- 1 dB. ESA

The possibility of performing absolute radiometric calibration of ERS-1 SAR (Synthetic Aperture Radar) Fast Delivery (FD) images is investigated. A 1.5 month time series during the first ice phase included fourteen satellite overpasses and showed that the radiometric stability of the SAR FD images was better than 0.3 dB (root mean square). A comparison with the average ESA calibration constant showed an average difference of 0.2 dB. The average difference obtained from a second calibration experiment during the commissioning phase was 0.9 dB, but included only two overpasses. It is pointed out that the FD product header does not provide sufficient information to determine the image geometry for across track calibration. Methods to solve this problem are suggested, but more work is needed to evaluate their performance. ESA

Satellite SAR (Synthetic Aperture Radar) data (ERS-1) and airborne SAR data (AIRSAR and PHARS) of the agriculture test site Flevoland in the Netherlands on coincident dates are studied. AIRSAR can be calibrated with an accuracy of about 1 dB and PHARS data with an accuracy of about 2 dB. The calibration accuracy for the ERS-1 data is on average 0.3 dB. The results show that these satellite and airborne SAR data can give consistent results despite their differences in resolution and speckle (number of looks). ESA

The main objective of the investigations carried out on images acquired during the commissioning phase of the ERS-1 life, was the quality assessment and calibration of image data. This required the availability of a set of targets of known radar scattering behavior, distributed over the imaged area in such a way to allow accurate analysis and calibration of the system response. The Institute for Remote Sensing Applications of the Joint Research Centre, in the frame of the International Forest Investigation project, selected the area of Freiburg Black Forest (Germany) as calibration site for the ERS-1 data. During the satellite commissioning phase, a set of three active radar calibrators were deployed on five dates, four weeks apart approximately, with location accuracy of 5 m. The first results achieved in the radiometric calibration and quality analysis of the ERS-1 images over the Black Forest show good agreement with the expected theoretical values of the impulse response function characteristics for the precision image product while the single look complex data sets processed presented saturation phenomena. ESA

AN EXPERIMENT FOR THE RADIOMETRIC CALIBRATION OF THE ERS-1 SAR
P. J. Bird, G. E. Keyte, and D. R. D. Kenward *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 195-200 Sponsored by British National Space Centre (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A02/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

The performance of 4 precision corner reflectors and a radome cover are assessed. Measurements made on the reflectors indicate a very rigid, accurate construction. From an analysis of ERS-1 SAR imagery, it is shown that the reflectors provide a calibration target of similar stability to that of the DRA ground based scatterometer transponder. Variations in the reflector image response were found, which are related to changes in the replica pulse power. The cause of the replica power changes are not known. A number of other reflectors were deployed and are used, together with the precision reflectors and transponder to demonstrate the good SAR (Synthetic Aperture Radar) system linearity. Grass and bare soil backgrounds are compared. It is shown that grass provides the more suitable calibration site. A good agreement between SAR and ground based scatterometer data is found. ESA

SAR (Synthetic Aperture Radar) interferometry allows the measurement of high resolution topography of terrain from repeat orbit SAR data sets obtained by the ERS-1 AMI (Active Microwave Instrument). The system parameters which affect the accuracy of the topographic maps are errors in determination of the interferometric baseline, non parallel orbit tracks, decorrelation caused by baseline length, thermal noise, and surface change. Surface change can be observed in the interferograms either through decorrelation of the interferometric phase, or coherent phase shifts caused by locally uniform surface displacements. Phase gradient maps can be derived directly from the complex interferograms and can be transformed into surface slopes mapped onto a geometrically corrected grid. ESA

Synthetic Aperture Radar (SAR) is a microwave coherent imaging system which has day, night and all weather capabilities. SAR coherence can be exploited for applications of repeated surveys like digital elevation map generation, improvement of ground range resolution, measurement of small changes of the terrain. ERS-1 SAR mission represents a good opportunity for testing these applications. The first experiments carried out with ERS-1 SAR Image mode on coherent multitemporal imaging applications are reported. ESA

The ERS-1 mission with its different orbit modes and excellent SAR (Synthetic Aperture Radar) performance offers particularly good opportunities to test and to promote the methods of SAR interferometry. Preliminary results are reported. For the Bonn (Germany) area it could be shown that the method of differential SAR interferometry allows very small height changes to be detected. The SAR interferometry allows, under proper physical conditions, both, the determination of the three dimensional topography and of the heights of forests, of buildings in settlements, and of other fine structured natural and man made targets. The preliminary results from the Antarctica show that the degree of correlation, and therefore of the coherence of the signals from an image pair can be used as a new measure for surface feature classification, and for change detection. Backscattering coefficients sigma(naught), measured by ERS-1 AMI (Active Microwave Instrument) in scatterometer mode, show significant regional variations over Antarctica. The angular dependence and magnitude of sigma(naught) are related to the morphology of the snow, enabling the discrimination of different snow regimes. Field measurements on backscattering signatures and on snow properties in Antarctica provide the basis for the interpretation of the ERS-1 scatterometer data. Examples of field data and satellite measurements are presented for refrozen firn on the ice shelves, homogeneous snow in high accumulation zones, and strongly stratified snow at the high plateaus. The use of ERS-1 altimeter fast delivery data to derive height maps of Greenland and Antarctica is reported. Without the off line waveform data it is not possible to correct these for tracker bias. However, over large areas of the ice sheets, this introduces an error which is small compared with the height resolution of our displays. Errors in the orbits and preliminary atmospheric corrections used were reduced by averaging data over multiple repeat cycles. For Greenland, a slope induced error correction was applied. The maps are the most accurate yet of the regions beyond +/- 72 deg. Preliminary results include the delineation of drainage basins on the Greenland ice sheet, and the observation of glaciologically interesting surface features in Antarctica. ESA

Mapping of Antarctica by the ERS-1 satellite is described. Remote sensing data of spaceborne sensors are able to give a multitude of geoscientific information on regions difficult or inaccessible at all for terrestrial survey programs. This is particularly true for Antarctica because of its geographic isolation and its environment, in general hostile towards life. Here ERS-1 and in particular its microwave sensors give reason to expect new and better research possibilities. Apart from the suitability of radar sensors for penetrating clouds, it will for the first time be possible to observe continuously the southern polar region during the austral winter. ESA

ERS-1 Synthetic Aperture Radar (SAR) imagery is shown to be suitable for monitoring the climate of the Greenland ice sheet and for measuring changes in its marginal position. Four distinct hydrologic zones are easily recognized. Zone boundaries align closely with elevation. Seasonal changes in at least one of these zones indicate that late Winter is a better time than late Summer for the collection of images intended for long term monitoring. Subtle variations of the backscatter intensity from the highest portions of the ice sheet where melting never occurs are believed to indicate surface topography. ESA

Accurate surface elevation data over the Antarctic ice sheet are needed to understand how the ice sheet is changing at present and to help determine how it might respond to future global climate change. Range measurements from the ERS-1 fast delivery data product were used to construct a preliminary map of surface elevation for Filchner-Ronne ice shelf. The map shows several important features related to processes controlling the movement of the ice shelf and its interaction with the underlying ocean. Elevation data over Berkner Island was compared to a digital elevation model constructed from airborne data and show slope induced errors of up to 50 m. Analysis of waveforms derived from raw data suggest that there is little tracker bias. ESA

Qualitative and quantitative analysis of several geocoded, precision and low resolution SAR (Synthetic Aperture Radar) images from a number of sites in Greenland, Svalbard and Franz Josef Land, are described. These images were acquired as part of ESA's program for the study of ice sheets and glaciers using ERS-1 data, and they will ultimately be compared with a wide variety of validating datasets in order to assess and model the response of a SAR system to the changing conditions of these elements of the Earth's surface. Preliminary analyses of these images are described, assessing their potential for mapping the two dimensional geometry of glacier fronts and of different surface facies (dry snow, wet snow, superimposed ice and bare glacier ice); for the detection of seasonal change in the position of the snow line; and for confirming the variation of the backscatter coefficient with incidence angle over snow covered surfaces. The drift velocities of icebergs calving from ice sheet outlet glaciers on Greenland can also be monitored. ESA

SPATIAL PATTERNS IN BACKSCATTER STRENGTH ACROSS THE GREENLAND ICE SHEET
K. C. Jezek *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 269-272 Sponsored by NASA, Washington (For primary document see N94-11704 01-43)

The relationship between the physical properties of the Greenland ice sheet and Synthetic Aperture Radar (SAR) data collected from aircraft and from ERS-1 is addressed. Limited aircraft data are combined with a description of the glacier surface to predict qualitatively the spatial and seasonal variation in backscatter strength across the ice sheet. In particular the model predicts relatively low backscatter near the ice edge where scattering is dominated by rough surface effects. Backscatter increases through the lake zone as volume scattering becomes important. Strongest backscatter is found in the percolation facies where volume scatter from snow grains and volume scatter from large, buried ice bodies becomes important. Backscatter weakens in the interior ice sheet where fine grained snow is the only mechanism producing backscatter. ESA

The Seasonal Ice Zone Experiment (SIZEX 92) is a sea ice validation program for ERS-1 SAR (Synthetic Aperture Radar). The main field experiment was carried out in the Barents Sea in Mar. 1992 using an ice strengthened vessel, a helicopter and a research vessel which operated in thin ice outside the main ice edge. In situ measurements, aerial photographs and video records were obtained from different ice types such as multiyear, firstyear, refrozen leads, pancake ice, grease ice and icebergs. Approximately 50 low resolution SAR scenes (100 m) and 5 full resolution SAR scenes (25 m) were obtained from ERS-1 during the experiment. The experiment showed that multiyear ice, which was more than 4 m thick, had generally higher SAR backscatter values than the firstyear ice in the interior of the ice pack. On the other hand, firstyear ice which dominated in a 30 to 40 km wide zone inside the ice edge had similar backscatter values as the multiyear ice. The lowest backscatter values were found in refrozen leads and in areas outside the ice edge where grease was formed. In addition to ice type classification the SAR images from ERS-1 were useful to characterize the ice edge, estimate ice concentration, locate leads/polynyas, find shear zones in the ice pack, quantify ice motion and map areas of new ice formation. A joint project among several European institutions is in progress to measure ice flux across the 79th and the 75th parallels of latitude, and hence estimate the fresh water flux into the northern Greenland sea. At 75 deg north a line of three upward looking moored sonars have been in place since Aug. 1991, renewed for a further year in Aug. 1992. ERS-1 SAR (Synthetic Aperture Radar) imagery is being used in conjunction with AVHRR (Advanced Very High Resolution Radiometer) to measure north-south ice velocity components across the width of east Greenland Current at 75 deg north with averaging of three days (Jan. to Mar. 1992) and a slightly longer, variable period after Mar. 1992 when the satellite entered a 35 day repeat orbit. By combining velocities and 3 day averaged ice thickness, both interpolated across the width of the current, it is possible to estimate the ice flux in an unbiased way. Initial results of the satellite work are reported, since the upward sonar thickness data are not yet available. ESA

Results from ARCTIC-91, the first field experiments to the high Arctic with simultaneous coverage of the ERS-1 SAR (Synthetic Aperture Radar) satellite, are reported. Results from the advanced melt period and early freeze-up period are given. Average sigma deg values as well as Delta-sigma deg/Delta-Theta over the image for different ice classification are given. Methods to derive ice concentration and the uncertainties in the procedure are investigated. Accuracy within a few percent seems to be possible during the late melt period, and results are in good agreement with the less good ship reports. Ice concentration estimates are important for climate change studies and for comparison with passive microwave sensors. An example illustrating complex ice motion phenomena derived from automatic routines is given. ESA

ARCTIC COASTAL POLYNYA OBSERVATIONS WITH ERS-1 SAR AND DMSP SSM/I

D. J. Cavalieri and R. G. Onstott (Environmental Research Inst. of Michigan, Ann Arbor.) *In* ESA, Proceedings of First ERS-1 Symposium on Space at the Service of Our Environment, Volume 1 Mar. 1993 p 295-299 (For primary document see N94-11704 01-43)
Copyright Avail: CASI HC A01/MF A04; EPD, ESA, ESTEC, Noordwijk, Netherlands, HC

Work to improve the characterization of the distribution of new and young sea ice types and open water amount within Arctic coastal polynyas through the combined use of ERS-1 SAR (Synthetic Aperture Radar) and DMSP SSM/I (Defense Meteorological Satellite Program Special Sensor Microwave/Imager) data is described. Two St. Lawrence Island polynya events are studied using low resolution, geocoded SAR images and coincident SSM/I data. The SAR images are analyzed in terms of polarization and spectral gradient ratios. Results of the combined analysis show that the SAR ice type classification is consistent with that from SSM/I and that the combined use of SAR and SSM/I can improve the characterization of thin ice better than either data set can do alone. The material properties of the sea ice cover are exhibited in the spatial structure of the field of ice motion. This structure is well sampled by sea ice displacements computed by a geophysical processor system at the Alaska SAR (Synthetic Aperture Radar) facility. Each pair of images can give rise to as many as 400 displacement vectors on a 5 km grid, with an average of about 200 vectors per pair. The data from about 1700 such image pairs was analyzed, and histograms of the average velocity derivatives and deformation invariants are shown. The estimate of mean vorticity in the Beaufort Gyre, for example, agrees with published results derived from buoy and ice station data. Values of divergence are found to have a mean of -0.002 and a standard deviation of 0.022/day. Mosaics of motion data some 1500 km long show the piece-like structure of field of motion. ESA
